[FRL-6337-1]

#### RIN 2060-AH97

#### Test Methods: Three New Methods for Velocity and Volumetric Flow Rate Determination in Stacks or Ducts

AGENCY: Environmental Protection Agency (EPA). ACTION: Direct final rule.

SUMMARY: EPA is taking direct final action to approve three new optional test methods for measuring velocity and volumetric flow rate of flue gas from fossil fuel-fired boilers and turbines. These new methods allow the tester to account for velocity drop-off near the stack or duct wall and the yaw and pitch angles of flow. The primary users of the new methods will be owners and operators of utility units subject to the Acid Rain Program under title IV of the Clean Air Act, and certain large electric generating units and large non-electric generating units that may become subject to the nitrogen oxides  $(NO_X)$ state implementation plan (SIP) call under Title I of the Clean Air Act, who must use an approved test method to periodically calibrate the flow rate monitors at these units. Flow rate data is used to determine the units' sulfur dioxide (SO<sub>2</sub>) and NO<sub>X</sub> mass emissions and heat inputs. The purpose of the Acid Rain Program and the NO<sub>X</sub> SIP call is to significantly reduce emissions from electric generating plants and other affected units in order to reduce the adverse health and environmental effects of acid deposition or ground level ozone resulting from these emissions.

The sources affected by this action are primarily in the sector Fossil Fuel Electric Power Generation, North American Industrial Classification System (NAICS) code 221112, or are industrial boilers. The affected sources include U.S. industry establishments primarily engaged in operating fossil fuel powered electric power generation facilities. These facilities use fossil fuels, such as coal, oil, or gas, in boilers and combustion turbines to produce electric energy or steam. The electric energy produced in these establishments are provided to electric power transmission systems or to electric power distribution systems.

**DATES:** This rule is effective on July 13, 1999 without further notice, unless EPA receives adverse comment by June 14, 1999. or (if a public hearing is requested) by July 1, 1999. If we receive such comment, we will publish a timely withdrawal in the **Federal Register** informing the public that this rule will not take effect.

ADDRESSES: Any written comments must be identified with Docket No. A-99-14, must be identified as comments on the direct final rule and companion proposal and must be submitted in duplicate to: EPA Air Docket (6102), Environmental Protection Agency, 401 M Street, SW, Washington, DC 20460. The docket is available for public inspection and copying between 8:30 a.m. and 3:30 p.m., Monday through Friday, at the address given above. A reasonable fee may be charged for copying. A detailed rationale for today's action is set forth in the Findings Report, which can be obtained by writing to the Air Docket at the address given above.

FOR FURTHER INFORMATION CONTACT: John Schakenbach, Acid Rain Division (6204J), U.S. Environmental Protection Agency, 401 M Street, SW, Washington, DC 20460, (202) 564–9158; or Elliot Lieberman, Acid Rain Division (6204J), U.S. Environmental Protection Agency, 401 M Street, SW, Washington, DC 20460, (202) 564–9136.

SUPPLEMENTARY INFORMATION: EPA is publishing this rule without prior proposal because we view these new test methods as noncontroversial and anticipate no adverse comment. We believe the rule is not controversial for the following reasons: (1) The rule is primarily technical in nature, (2) the rule is generally accepted by the scientific community, and (3) use of the new test methods will be optional. However, we are publishing a separate document that will serve as the proposal to approve the test methods if adverse comments are filed. This rule will be effective on July 13, 1999 without further notice unless we receive adverse comment by June 14, 1999 or (if a public hearing is requested) by July 1, 1999. If EPA receives timely adverse comment, we will publish a withdrawal in the Federal Register informing the public that the rule will not take effect. We will address all public comments in a subsequent final rule based on the proposed rule. We will not institute a second comment period on this action. Any parties interested in commenting must do so at this time.

#### **II. Regulated Entities**

Entities potentially regulated by this action are utility and industrial fossil fuel-fired boilers and turbines that serve generators producing electricity, generate steam, or cogenerate electricity and steam and that are subject to EPA's monitoring regulations, 40 CFR part 75. While part 75 primarily regulates the electric utility industry, today's action could potentially affect other industries, including those subject to the NO<sub>X</sub> SIP call. Regulated categories and entities include:

Category	Examples of regulated entities
NAICS Code: 221112, Fossil Fuel Electric Power Generation	Electric service providers, boilers and turbines from a wide range of industries.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be regulated by this action. This table lists the types of entities which EPA is now aware could potentially be regulated by this action. Other types of entities not listed in the table could also be regulated. To determine whether your facility, company, business, organization, etc., is regulated by this action, you should carefully examine the applicability criteria in §§ 72.6, 72.7, 72.8, 75.70, and Appendix A of part 60 of title 40 of the Code of Federal Regulations. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the preceding "For Further Information Contact" section of this preamble.

#### II. Background

In 1971, EPA promulgated Method 2 "Determination of Stack Gas Velocity and Volumetric Flow Rate (Type S Pitot Tube)". At the time of its development, Method 2 was principally used with EPA Method 5 "Determination of Particulate Emissions from Stationary Sources" to help ensure appropriate sampling rates throughout a particulate sampling run.

Many EPA air quality regulations use Method 2, including part 75 of EPA's Acid Rain Program regulations, implementing title IV of the Clean Air Act (the Act), and part 51 of EPA's NOx SIP call, which may result in states or EPA requiring certain large electric generating units and large non-electric generating units to comply with subpart H of part 75. See 40 CFR parts 51 and 75; and 63 FR 57356, 57495, October 27, 1998. Part 75 requires affected electric utility units to install and operate continuous emission monitoring systems that provide EPA with continuous hourly measurements of sulfur dioxide  $(SO_2)$  concentration, NO<sub>X</sub> concentration, carbon dioxide concentration, and volumetric flow rate of flue gas in a stack or duct. Under the Acid Rain Program, volumetric flow rate and SO<sub>2</sub> concentration are used to calculate sulfur dioxide mass emissions at each affected unit. At the end of each year, these emissions are compared to the unit's sulfur dioxide allowances to determine whether the unit held enough allowances to cover its emissions. Volumetric flow rate is also used to calculate a unit's heat input. In order to ensure the accuracy of compliance determinations, part 75 requires owners and operators of a unit to conduct periodic performance testing of volumetric flow rate monitors by comparing flow rate data from the monitors with data reported using EPA's Method 2. Similarly, subpart H of part 75 uses Method 2 as the reference method for flow rate measurements used to calculate NO<sub>x</sub> mass emissions. See also 40 CFR part 96.

In the first three years of the Acid Rain Program, the electric utility industry raised concerns that under some flow conditions EPA's approved test method for volumetric flow rate (Method 2) could be less than optimal for measuring flow rate and thus for determining sulfur dioxide emissions and heat input. These concerns focused on situations where flue gas flowed at an angle (i.e., with yaw or pitch), not straight out of a stack or duct. Method 2 does not include procedures for measuring the yaw or pitch angles of flow or wall effects in calculating stack or duct gas velocity or volumetric flow rate.

Volumetric flow rate is calculated by multiplying the average flue gas velocity by the stack or duct cross-sectional area. Yaw and pitch characterize the extent to which flue gas is not flowing straight out of a stack or duct. From the standpoint of a tester facing a vertical stack, a yaw angle is represented by flow movement to the left or right of the stack centerline. The pitch angle is represented by flow movement toward or away from the tester. The term "wall effects" refers to the drop-off of flue gas velocity near the inside wall of a stack or duct. This velocity drop-off is caused by friction from the stack wall.

Some amount of yaw and pitch angle and wall effects are almost always present in utility stacks or ducts. Yaw and pitch angles produce flue gas flow that swirls and/or bounces off stack or duct walls (total velocity). Only the straight-up (axial velocity) component of total velocity actually exits the stack. Moreover, determining axial velocity without accounting for the drop-off near the stack or duct wall can result in overstating the actual axial velocity. Thus, when enough yaw, pitch or wall effects are present, Method 2 can overstate the measured flue gas velocities (and thus volumetric flow) because it only allows the total velocity to be measured and does not account for vaw angles, pitch angles, or wall effects. If the test method overstates flow rate, a flow rate monitor calibrated using the test method may also overstate flow rate and result in overstated sulfur dioxide emissions and heat input.

To address these concerns, and to provide a technical basis for potential new test methods, EPA initiated a flow study consisting of wind tunnel tests and field tests. Wind tunnel tests were performed to ensure accurate probe calibrations, to determine probe performance under different temperature conditions (Reynolds number testing), and to determine probe performance under different flow angle conditions (swirl tunnel testing). Probe calibrations were performed at three wind tunnel facilities: the North Carolina State University (NCSU), the National Institute of Standards and Technology, and the Massachusetts Institute of Technology (MIT). The Reynolds number testing was conducted at MIT. The swirl tunnel testing was performed by the Fossil Energy Research Corporation at a special wind tunnel installation developed for the Electric Power Research Institute.

In addition, field tests were performed to evaluate new techniques that could improve the ability to measure flow rate under a wide range of conditions and to provide a technical basis for potential, new test methods. Field tests were performed at two natural gas-fired 750 MWe electric utility boilers and at a 640 MWe bituminous coal-fired utility boiler. These three sites were selected to provide three different flow swirl conditions. Four test teams were used at each site to perform simultaneous testing of various probes. In this manner, probes could be tested under essentially the same conditions. Seven different probes types were tested: Type S, United Sciences Testing Incorporated Autoprobe Type S, Prandtl (Standard

Pitot), French, modified Kiel, DAT, and spherical. A Codel flow monitor was also tested.

A special series of tests were also performed to investigate velocity dropoff near stack walls. These wall effects tests were performed at five sites. The sites were selected to provide different inside stack wall material (steel and brick and mortar) and stack gas flow conditions in order to test how these parameters affect stack gas velocity drop-off near the stack wall.

As a result of the wind tunnel tests and field tests, a report describing results of the wind tunnel testing, three Site Data Reports, describing test activities and results at each site, and the Findings Report, describing overall conclusions, were written. These reports are included in the docket. Significant findings from the wind tunnel and field tests are:

• Probes that could determine the yaw and pitch angles of flow produced results closer to those predicted by scientific theory;

• Overall, the Type S, Autoprobe Type S, DAT, and spherical probes produced the best results: they tended to be less variable, did not consistently under-measure velocity, and were closer to theoretically derived results and the central tendency of the data than the other probes tested;

• Automated probes were less variable than manually operated probes;

• Several probes (modified Kiel, and the French) and the Codel flow monitor produced highly variable test results and should not be included in new test methods;

• Measuring wall effects produced a 1/2% to 3% improvement in volumetric flow rate measurements.

• The amount of wall effect is lower for stacks with smooth interiors (steel) than for stacks with rougher interiors (brick and mortar);

• To produce reliable probe calibrations, wind tunnels should meet certain specifications related to tunnel size and flow conditions;

• Calibration curves for threedimensional (3–D) probes, i.e., DAT and the spherical probes, are less reliable for velocities below 20 feet per second; and

• Contrary to expectations, scratches on the surface of spherical probes did not significantly effect their calibrations. We used these data and findings to develop the three new test methods described in today's rulemaking.

Review by independent experts, industry experts, and EPA experts was used in the three major phases of the flow study: The field test plan, the draft Findings Report, and the three draft test 26486

methods. One significant comment by the reviewers was that we should keep the new test methods as effective and practical as possible, but still provide flexibility and a wide range of options for stack testers. Based on reviewer feedback on subsequent versions of the test methods, we believe we have accommodated all major concerns.

#### III. Approval of Three New Test Methods

Today's direct final rule approves three new test methods that provide probes and procedures to account for yaw angles, pitch angles and wall effects. Method 2G allows Type S probes and 3-D probes (DAT and spherical) to be rotated into the flow to measure total velocity pressure and yaw angle. The yaw angle is used to calculate "near-axial" velocity from total velocity. Method 2F allows 3-D probes to be used to measure total velocity, yaw angles, and pitch angle pressure. Pitch angle pressure is used with a calibration curve to determine pitch angle. Yaw and pitch angles are used to calculate axial velocity from total velocity. Method 2H provides a procedure for accounting for wall effects by using either a default wall effects adjustment factor or one derived from near wall measurements. The wall effects adjustment factor is used with the Method 2-, 2G- or 2F-calculated velocity to derive a wall effects adjusted velocity.

In the Acid Rain Program, and in other programs which require reporting of mass emission rates (e.g., lbs NO<sub>x</sub>/ hour), a capability to measure these parameters in the calculation of volumetric flow rate can improve the reporting of pollutant emissions in some situations (described earlier). In addition, the new test methods in today's rulemaking address the disparity that has sometimes been reported between heat rate calculated using a flow monitor and heat rate calculated using fuel sampling and analysis to the extent that the disparity results from the difficulty of measuring flue gas flow rate under certain flow conditions. This rule does not address the procedures used in fuel sampling or in the calculation of heat rate.

EPA is voluntarily undertaking this regulatory action in response to requests from the regulated community. This regulatory action provides additional accepted scientific and analytical methods for measuring volumetric flow rate in stacks and ducts The additional test methods are the result of extensive field studies that were subjected to review by a panel of independent experts, utility company representatives, and internal EPA staff. These new test methods may be used instead of Method 2 in programs that use part 75 or part 96 procedures to quantify emissions. These new test methods are discussed below in detail.

#### A. Methods 2F and 2G

Method 2F, "Determination of Stack Gas Velocity and Volumetric Flow Rate With Three-Dimensional Probes", is a method for measuring the yaw and pitch angle-adjusted (or axial) velocity with 3dimensional probes like the prismshaped, five-hole probe (commonly called a DA or DAT probe) and the fivehole spherical probe. Method 2G, "Determination of Stack Gas Velocity and Volumetric Flow Rate With Two-Dimensional Probes", is a variant of existing Method 2 that describes the use of yaw angle determination procedures with Type S or 3-dimensional probes to determine the yaw angle-adjusted flue gas velocity in a stack or duct.

The methods include step-by-step procedures specifically designed to provide quality assured measurements and address a number of key problems uncovered in the course of the wind tunnel and field testing of the new methods. The following summarizes the major steps for performing Method 2F or 2G.

#### (1) Qualify Wind Tunnel

The wind tunnel tests revealed that some wind tunnels used by vendors or source testers to calibrate probes were inadequate, because they were either too small or did not have uniform flow. To avoid such problems, any wind tunnel used to calibrate probes for Methods 2F or 2G must satisfy certain design and performance specifications to ensure that the flow is axial (straight) and uniform in the wind tunnel calibration location. The wind tunnel must meet two design criteria: (1) The diameter must be at least 12 inches; and (2) the projected area of the tested probe and reference calibration pitot tube must not exceed 4% of the cross-sectional area of the wind tunnel. The wind tunnel must also meet two performance specifications: (1) A velocity pressure cross-check to ensure that the velocity is the same at all locations where the tested and reference probes will be positioned during calibration; and (2) an axial flow verification to ensure that there are no significant yaw or pitch components of flow at these locations. These two tests are performed before the initial use of the wind tunnel and are repeated after any alterations are made to the tunnel.

#### (2) Prepare To Calibrate Probe

The wind tunnel and field tests also showed that pre-calibration probe inspection and procedures for placing a scribe line on a probe were important prerequisites for accurate yaw angle measurements. Therefore, the methods include the following five general activities to be performed prior to calibrating a probe (1) Put a straight permanent line (scribe line) on the probe. This activity only needs to be performed once, not every time a probe is calibrated. The scribe line must meet certain straightness and width criteria so that a yaw angle measuring device can be accurately placed on the probe. (2) Check that the probe is not bent and does not have significant sag. (3) Pressure devices must be zeroed and calibrated. (4) The yaw angle measurement device must be calibrated and aligned relative to the reference scribe line. (5) The probe system must be leak checked.

### (3) Perform Yaw Angle Calibration

Yaw angle errors were observed in the wind tunnel tests when the offset of the scribe line from the probe's zero yaw position was not accurately determined in the wind tunnel. The methods, therefore, include a yaw angle calibration procedure, which must be performed on the complete probe assembly in a wind tunnel to determine the "reference scribe line rotational offset" angle (R<sup>slo</sup>). The R<sup>slo</sup> indicates the rotational position of a probe's reference scribe line relative to the probe's yawnull position and is used in determining the yaw angle of flow in a stack or duct.

# (4) Perform Velocity and Pitch Calibrations

The field and wind tunnel tests showed that robust velocity and pitch calibration procedures were required if errors in velocity and volumetric flow determinations are to be avoided. For Method 2G, this consists of a wind tunnel procedure to determine a velocity calibration coefficient for the tested probe. This calibration coefficient is used to calculate stack gas velocity from pressure measurements taken in the field. The velocity calibration procedure involves taking three pairs of pressure measurements with the tested probe and a reference calibration pitot tube at two wind tunnel velocity settings. Calibration coefficients obtained at wind tunnel velocity settings of 60 and 90 feet per second (fps) are usable in all field applications where the velocities are 30 fps or greater. Calibration coefficients derived at other velocity settings are usable in

field applications where the measured velocity does not fall outside the limits defined by those velocity settings.

Method 2F includes wind tunnel procedures to determine both velocity and pitch angle calibration curves. These curves are used to determine both the pitch angle and velocity of flue gas flow when using a 3-dimensional probe. The pitch and velocity calibration procedure involves positioning the tested probe at a series of pitch angles settings relative to the flow in the wind tunnel and then taking pressure measurements with the tested probe and a reference probe. The measurements are repeated at two wind tunnel velocity settings. Calibration curves obtained at wind tunnel velocity settings of 60 and 90 fps are usable in all field applications over the entire velocity range allowed by the method. Calibration curves derived at other velocity settings are usable in all field applications allowed by the method as long as the measured velocity does not exceed both of the wind tunnel velocity settings used to derive the curves.

#### (5) Prepare for Field Test

The field tests showed that the inspection of probes and the set-up procedures described above under step 2 were not only a critical prerequisite for wind tunnel testing, but were equally important in field testing. For example, during one of the field tests, an inspection detected damage to the probe head which resulted in spurious readings from a probe. Thus, prior to beginning a field test, each method requires performance of all the checks described in item 2 ("Prepare to Calibrate Probe'') above, except for putting a scribe line on the probe. Additionally, the tester must inspect the probe for damage, mark traverse point distances on the probe, and determine a system response time.

#### (6) Perform Field Test

The field tests also showed that the quality of measurements was affected by procedures followed by testers when performing the field tests. For example, allowing sufficient response time and checking for probe plugging were shown to be important considerations during the field test. Thus, the methods give specific instructions on how to perform a field test. In particular, the methods instruct testers to perform the following steps. Insert the probe into a test port in the stack or duct, and move the probe to the first traverse point. After the system response time has elapsed, measure the yaw angle, impact pressure, and pitch angle pressure (Method 2F only). Take these measurements at each

traverse point of the run. In addition, measure barometric pressure, flue gas molecular weight, moisture and static pressure. Check the probe periodically for plugging to prevent erratic results or sluggish responses.

#### (7) Perform Calculations

To account for pitch and yaw components of flow, the methods had to include new calculation procedures that were not needed in Method 2. These procedures were employed in the field tests and shown to be workable. They include calculating the pitch angle (Method 2F only) and impact velocity at each traverse point using the pressure measurements taken in the field and the calibration coefficient (Method 2G) or curves (Method 2F) derived in the wind tunnel. Using these values and the yaw angles measured in the field, the axial velocity (Method 2F) or yaw-adjusted velocity (Method 2G) is calculated at each traverse point. Stack or duct average velocity is then calculated by averaging over all the traverse point velocities. Checks are performed to see that the calibration coefficients or curves are appropriate for the velocity encountered in the field. Finally, the volumetric flow rate is derived by multiplying the stack or duct crosssectional area and the average velocity.

#### B. Method 2H

Method 2H, "Determination of Stack Gas Velocity Taking into Account Velocity Decay Near the Stack Wall", can be used in conjunction with existing Method 2 or new Methods 2F or 2G to account for velocity drop-off near stack (or duct) walls in circular stacks (or ducts) no less than 3.3 feet in diameter. Method 2H is not suitable for use in rectangular stacks or ducts because the procedures in this method are not applicable to the complex and varying flow dynamics characteristic of such configurations.

There are two main approaches for determining wall effects adjusted velocity in Method 2H. Either a default wall effects adjustment factor (WAF) (i.e., 0.9900 (for brick and mortar stacks), or 0.9950 (for all other stacks or ducts)) may be used with Method 2, 2F, or 2G without taking any wall effects measurements or a WAF may be calculated from velocity measurements taken at 16 or more Method 1 traverse points and at 8 or more wall effects points. EPA's Method 1, "Sample and Velocity Traverses for Stationary Sources", is the test method for determining the number and location of traverse points in a stack or duct. Method 1 alone is generally not suitable for determining wall effects.

During the course of wall effects field testing, several potential problems were uncovered. Procedures were incorporated into Method 2H to prevent these problems. These are described below.

#### (1) Locate Traverse Points

The field test revealed that care needs to be exercised when locating wall effects traverse points; otherwise, the full wall effect may not be measured. Thus, Method 2H instructs testers to take measurements at 1-inch intervals starting at 1 inch from the wall or at the next closest 1-inch interval from the wall possible. Testers may perform either a partial or complete wall effects traverse. For a partial traverse, measurements are taken at two wall effects traverse points per test port, at a minimum. For a complete traverse, a series of 1-inch incremented measurements are taken beginning no further than 4 inches from the wall and extending in 1-inch intervals as far as 12 inches from the wall. The method presents procedures for determining the location of the wall effects points.

#### (2) Determine Sampling Order

Field tests also showed that an incorrect WAF may be calculated if the wall effects sampling is decoupled from the Method 1 sampling. Therefore, the method includes instructions on how sampling is to be performed. The sampling order may be from the wall to the center or from the center to the wall. Although the Method 1 and wall effects points need not be interspersed at each port, there should be no interruption between sampling at the wall effects and Method 1 points. The intent of this sampling sequence is to keep the Method 1 and the wall effects measurements as close together in time as possible to reduce the possibility of different velocity conditions occurring during the Method 1 and wall effects measurements.

#### (3) Take and Record Measurements

As in Methods 2F and 2G, field tests showed that the procedures followed by testers were critical to the quality of the measurements obtained. Wall effects testing not only required the procedures found in Method 2F and 2G, but also additional procedures for taking measurements close to a stack or duct wall. For example, the method had to include instructions for testing in situations where it may not be possible to obtain measurements within a certain proximity (e.g., 1 inch) of the stack or duct wall. Method 2H instructs testers to perform the following steps. After inserting the probe into the gas stream,

wait for the pressure and temperature readings to stabilize to stack or duct conditions before taking measurements at the first traverse point. (This time period is called the "system response time" and is defined in Methods 2F and 2G.) At all other traverse points, testers must allow enough time to obtain representative pressure measurements. If no velocity is detected at the wall effects point closest to the wall, move to the next 1-inch incremented wall effects point. Complete the integrated traverse as quickly as possible, consistent with adequate sampling time, so that the measurements are all taken under the same stack or duct conditions. In addition, take other measurements required by Method 2, 2F, or 2G (e.g., moisture, barometric pressure). Record all measurements.

#### (4) Perform Wall Effects Calculations

The field tests confirmed that a series of measurements near a stack wall could capture the impact of wall effects on flue gas flow in a stack or duct. To capture this effect, a new calculation procedure was developed which was tested in the field. This procedure was incorporated in Method 2H. It involves calculating the velocity at each wall effects traverse point and entering the resulting values in a table. The entered values are then used to find the wall effects-adjusted replacement velocities for the four Method 1 traverse points closest to the wall. These four values and the unadjusted velocity at the Method 1 traverse points are used to calculate a WAF. The WAF is a multiplier which can then be applied to the velocity derived using Methods 2, 2F, and 2G to account for velocity decay near the stack or duct wall. The WAF may be no less than 0.9800 for a partial traverse and no less than 0.9700 for a complete traverse. We derived these limits from analysis of wall effects tests performed on a variety of utility stacks (different stack lining material, velocities, and stack dimensions). If actual field testing indicates that the WAF for a particular stack or duct may be less than 0.970, the tester should increase the number of traverse points in the Method 1 traverse (e.g., to 20 or 24 points if a 16-point traverse was initially performed) and re-calculate the WAF to capture the full extent of the wall effect.

#### (5) Obtain Wall Effects Adjusted Velocity and Volumetric Flow Rate

While the field test showed the calculation procedures to be effective, the new test method also needed to clarify how WAFs were to be applied to calculate the wall effects adjusted

volumetric flow rate for the stack or duct. Thus, the final steps in Method 2H include instructions on how to calculate the wall effects adjusted velocity for the stack or duct by multiplying the unadjusted velocity from Method 2, 2F, or 2G by the WAF (either calculated or default). The calculated WAF from one run may be applied to all runs of the same relative accuracy test audit (RATA). If calculated WAFs are obtained for several runs, the tester must average the WAFs and apply the resulting value to all runs of the same RATA. The stack or duct volumetric flow rate is then obtained by multiplying the wall effects adjusted velocity by the stack or duct crosssectional area.

#### **IV. Administrative Requirements**

#### A. Executive Order 12866

Under Executive Order 12866 (58 FR 51735, October 4, 1993), the Administrator must determine whether the regulatory action is "significant" and therefore subject to Office of Management and Budget (OMB) review and the requirements of the Executive Order. The Order defines "significant regulatory action" as one that is likely to result in a rule that may:

(1) Have an annual effect on the economy of \$100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local or tribal governments or communities;

(2) Create a serious inconsistency or otherwise interfere with an action taken or planned by another agency;

(3) Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or

(4) Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

This action is not expected to have an annual effect on the economy of \$100 million or more. Pursuant to the terms of Executive Order 12866, it has been determined that this direct final rule is not a significant action. As such, the direct final rule has not been submitted for OMB review.

Today's action provides options for applying scientific and analytical methods generally accepted by the scientific community. The options provided by this action are not precedential, but typical of the periodic improvements the Agency routinely makes to test methods based on advances in technology, science, and field experience. In keeping with past practice, we are retaining existing methods while offering new methods to provide the regulated community with additional choices and to lower the cost of compliance.

Since use of the new methods is voluntary, we anticipate that the new methods will be used only if they result in overall cost savings. While the cost of performing the new methods may be somewhat higher than the existing test method (due to higher probe calibration costs, increased stack testing time, and additional test equipment), these costs should be completely offset by compliance cost savings.

# *B. Executive Order 12875: Enhancing Intergovernmental Partnerships*

Under Executive Order 12875, Enhancing Intergovernmental Partnerships, EPA may not issue a regulation that is not required by statute and that creates a mandate upon a State, local or tribal government, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by those governments, or EPA consults with those governments. If EPA complies by consulting, Executive Order 12875 requires EPA to provide to OMB a description of the extent of EPA's prior consultation with representatives of affected State, local and tribal governments, the nature of their concerns, copies of any written communications from the governments, and a statement supporting the need to issue the regulation. In addition, Executive Order 12875 requires EPA to develop an effective process permitting elected officials and other representatives of State, local and tribal governments "to provide meaningful and timely input in the development of regulatory proposals containing significant unfunded mandates.

As discussed above, today's direct final rule is voluntary and does not create a mandate on State, local or tribal governments. The rule does not impose any enforceable duties on these entities, unless they choose to use the new optional methods. Accordingly, the requirements of section 1(a) of Executive Order 12875 do not apply to this rule.

# *C. Executive Order 13084: Consultation and Coordination With Indian Tribal Governments*

Under Executive Order 13084, Consultation and Coordination with Indian Tribal Governments, EPA may not issue a regulation that is not required by statute, that significantly or uniquely affects the communities of Indian tribal governments, and that

imposes substantial direct compliance costs on those communities, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by the tribal governments, or EPA consults with those governments. If EPA complies by consulting, Executive Order 13084 requires EPA to provide to OMB, in a separately identified section of the preamble to the rule, a description of the extent of EPA's prior consultation with representatives of affected tribal governments, a summary of the nature of their concerns, and a statement supporting the need to issue the regulation. In addition, Executive Order 13084 requires EPA to develop an effective process permitting elected officials and other representatives of Indian tribal governments "to provide meaningful and timely input in the development of regulatory policies on matters that significantly or uniquely affect their communities.

Today's direct final rule does not significantly or uniquely affect the communities of Indian tribal governments. Today's action finalizes test method procedures for determining volumetric flow rate in stacks or ducts. Since use of the new methods is voluntary, we anticipate that the new methods will be used only if they result in overall cost savings. While the cost of performing the new methods may be somewhat higher than the existing test method (due to higher probe calibration costs, increased stack testing time, and additional test equipment), these costs should be completely offset either by compliance cost savings or increased compliance certainty. Accordingly, the requirements of section 3(b) of Executive Order 13084 do not apply to this rule.

#### D. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA). P.L. 104-4, establishes requirements for Federal agencies to assess the effects of their regulatory actions on State, local, and tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with "Federal mandates" that may result in expenditures to State, local, and tribal governments, in the aggregate, or to the private sector, of \$100 million or more in any one year. Before promulgating an EPA rule for which a written statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-

effective, or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows EPA to adopt an alternative other than the least costly, most cost-effective, or least burdensome alternative if the Administrator publishes with the final rule an explanation why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including tribal governments, it must have developed under section 203 of the UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments, enabling officials of affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small governments on compliance with the regulatory requirements.

Today's direct final rule is not expected to result in expenditures of more than \$100 million in any one year and, as such, is not subject to section 202 of the UMRA. The direct final rule is not expected to significantly or uniquely affect small governments.

#### E. Paperwork Reduction Act

Today's direct final rule will not add any additional information collection requirements to the current information collection requirements in the implementing regulations, e.g., part 75. Therefore an Information Collection Request was not prepared for the direct final rule.

An agency may not conduct or sponsor and a person is not required to respond to a collection of information, unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations are listed in 40 CFR part 9 and 48 CFR chapter 15.

#### F. Regulatory Flexibility

The Regulatory Flexibility Act, 5 U.S.C. 601, *et seq.*, generally requires an agency to conduct a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Small entities include small businesses, small not-forprofit enterprises, and governmental jurisdictions. EPA has determined that it is not necessary to prepare a regulatory flexibility analysis in connection with this direct final rule. EPA has also determined that this rule will not have a significant economic impact on a substantial number of small entities.

Since use of the new test methods is voluntary, we anticipate that the new options will be used only if they result in overall cost savings. While the cost of performing the new options may be somewhat higher than the existing test method (due to higher probe calibration costs, increased stack testing time, and additional test equipment), these costs should be completely offset by compliance cost savings.

### G. Executive Order 13045

"Protection of Children From Environmental Health Risks and Safety Risks'' (62 FR 19885, April 23, 1997) applies to any rule that: (1) Was initiated after April 21, 1997, or for which a Notice of Proposed Rulemaking was published after April 21, 1998; (2) is determined to be "economically significant" as defined under E.O. 12866, and (3) concerns an environmental health or safety risk that EPA has reason to believe may have a disproportionate effect on children. If the regulatory action meets all three criteria, the Agency must evaluate the environmental health or safety effects of the planned rule on children and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the Agency.

EPA interprets Executive Order 13045 as applying only to those regulatory actions that are based on health or safety risks, such that the analysis required under section 5–501 of the Executive Order has the potential to influence the regulation. This direct final rule is not subject to the Executive Order because the rule does not establish an environmental standard intended to mitigate health or safety risks.

# *H. National Technology Transfer and Advancement Act*

Section 12(d) of the National Technology Transfer and Advancement Act of 1995 ("NTTAA"), Pub L. 104-113 15 U.S.C. 272 note, directs EPA to use voluntary consensus standards in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impractical. Voluntary consensus standards are technical standards (e.g., materials specifications, test methods, sampling procedures, business practices) that are developed or adopted by voluntary consensus standards bodies. The NTTAA requires EPA to provide Congress, through OMB, explanations when the Agency decides

not to use available and applicable voluntary consensus standards.

EPA has not identified any voluntary consensus standards which might be applicable to this rulemaking.

#### I. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 et seq., as added by the Small **Business Regulatory Enforcement** Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the Federal Register. A major rule cannot take effect until 60 days after it is published in the Federal Register. This action is not a "major rule" as defined by 5 U.S.C. § 804(2). This rule will be effective on July 13, 1999.

### List of Subjects in 40 CFR Part 60

Air pollution control, Carbon dioxide, Continuous emission monitors, Electric power plants, Environmental protection, Nitrogen oxides, Particulate matter, Reporting and recordkeeping requirements, Sulfur dioxide.

Dated: May 5, 1999.

#### Carol M. Browner,

#### Administrator.

For the reasons set out in the preamble, title 40 chapter 1 of the Code of Federal Regulations is amended as follows:

#### PART 60—[AMENDED]

1. The authority citation for part 60 continues to read as follows:

**Authority:** 42 U.S.C. 7401, 7411, 7413, 7414, 7416, 7429, 7601 and 7602.

2. Appendix A is amended in the introductory table of contents by adding in alphanumeric order Methods 2F, 2G and 2H and by adding Methods 2F, 2G and 2H to Appendix A to read as follows:

#### Appendix A to Part 60—Test Methods

\* \* \* \* \* \* ''Method 2F—Determination of Stack Gas Velocity and Volumetric Flow Rate With Three-Dimensional Probes''

"Method 2G—Determination of Stack Gas Velocity and Volumetric Flow Rate With Two-Dimensional Probes"

"Method 2H—Determination of Stack Gas Velocity Taking Into Account Velocity Decay Near the Stack Wall"

\* \* \* \* \*

#### Method 2F—Determination of Stack Gas Velocity And Volumetric Flow Rate With Three-Dimensional Probes

**Note:** This method does not include all of the specifications (e.g., equipment and supplies) and procedures (e.g., sampling) essential to its performance. Some material has been incorporated from other methods in this part. Therefore, to obtain reliable results, those using this method should have a thorough knowledge of at least the following additional test methods: Methods 1, 2, 3 or 3A, and 4.

#### 1.0 Scope and Application

1.1 This method is applicable for the determination of yaw angle, pitch angle, axial velocity and the volumetric flow rate of a gas stream in a stack or duct using a threedimensional (3–D) probe. This method may be used only when the average stack or duct gas velocity is greater than or equal to 20 ft/ sec. When the above condition cannot be met, alternative procedures, approved by the Administrator, U.S. Environmental Protection Agency, shall be used to make accurate flow rate determinations.

#### 2.0 Summary of Method

2.1 A 3–D probe is used to determine the velocity pressure and the yaw and pitch angles of the flow velocity vector in a stack or duct. The method determines the yaw angle directly by rotating the probe to null the pressure across a pair of symmetrically placed ports on the probe head. The pitch angle is calculated using probe-specific calibration curves. From these values and a determination of the stack gas density, the average axial velocity of the stack gas is calculated. The average gas volumetric flow rate in the stack or duct is then determined from the average axial velocity.

#### 3.0 Definitions

3.1. Angle-measuring Device Rotational Offset ( $R_{ADO}$ ). The rotational position of an angle-measuring device relative to the reference scribe line, as determined during the pre-test rotational position check described in section 8.3.

3.2 Axial Velocity. The velocity vector parallel to the axis of the stack or duct that accounts for the yaw and pitch angle components of gas flow. The term "axial" is used herein to indicate that the velocity and volumetric flow rate results account for the measured yaw and pitch components of flow at each measurement point.

3.3 *Calibration Pitot Tube.* The standard (Prandtl type) pitot tube used as a reference when calibrating a 3–D probe under this method.

3.4 *Field Test.* A set of measurements conducted at a specific unit or exhaust stack/duct to satisfy the applicable regulation (e.g., a three-run boiler performance test, a single-or multiple-load nine-run relative accuracy test).

3.5 *Full Scale of Pressure-measuring Device.* Full scale refers to the upper limit of the measurement range displayed by the device. For bi-directional pressure gauges, full scale includes the entire pressure range from the lowest negative value to the highest positive value on the pressure scale. 3.6 *Main probe.* Refers to the probe head and that section of probe sheath directly attached to the probe head. The main probe sheath is distinguished from probe extensions, which are sections of sheath added onto the main probe to extend its reach.

3.7 *"May," "Must," "Shall," "Should,"* and the imperative form of verbs.

3.7.1 *"May"* is used to indicate that a provision of this method is optional.

3.7.2 *"Must," "Shall,"* and the imperative form of verbs (such as "record" or "enter") are used to indicate that a provision of this method is mandatory.

3.7.3 *"Should"* is used to indicate that a provision of this method is not mandatory, but is highly recommended as good practice.

3.8 *Method 1.* Refers to 40 CFR part 60, appendix A, "Method 1—Sample and

velocity traverses for stationary sources." 3.9 *Method 2.* Refers to 40 CFR part 60, appendix A, "Method 2—Determination of

appendix A, Method 2—Determination of stack gas velocity and volumetric flow rate (Type S pitot tube)."

3.10 *Method 2G.* Refers to 40 CFR part 60, appendix A, "Method 2G—Determination of stack gas velocity and volumetric flow rate with two-dimensional probes."

3.11 Nominal Velocity. Refers to a wind tunnel velocity setting that approximates the actual wind tunnel velocity to within  $\pm 1.5$  m/ sec ( $\pm 5$  ft/sec).

3.12 *Pitch Angle.* The angle between the axis of the stack or duct and the pitch component of flow, i.e., the component of the total velocity vector in a plane defined by the traverse line and the axis of the stack or duct. (Figure 2F–1 illustrates the "pitch plane.") From the standpoint of a tester facing a test port in a vertical stack, the pitch component of flow is the vector of flow moving from the center of the stack toward or away from that test port. The pitch angle is the angle described by this pitch component of flow and the vertical axis of the stack.

3.13 *Readability.* For the purposes of this method, readability for an analog measurement device is one half of the smallest scale division. For a digital measurement device, it is the number of decimals displayed by the device.

3.14 *Reference Scribe Line.* A line permanently inscribed on the main probe sheath (in accordance with section 6.1.6.1) to serve as a reference mark for determining yaw angles.

3.15 Reference Scribe Line Rotational Offset ( $R_{SLO}$ ). The rotational position of a probe's reference scribe line relative to the probe's yaw-null position, as determined during the yaw angle calibration described in section 10.5.

3.16 *Response Time.* The time required for the measurement system to fully respond to a change from zero differential pressure and ambient temperature to the stable stack or duct pressure and temperature readings at a traverse point.

3.17 *Tested Probe.* A 3–D probe that is being calibrated.

3.18 *Three-dimensional (3–D) Probe.* A directional probe used to determine the velocity pressure and yaw and pitch angles in a flowing gas stream.

3.19 *Traverse Line.* A diameter or axis extending across a stack or duct on which

measurements of differential pressure and flow angles are made.

3.20 Wind Tunnel Calibration Location. A point, line, area, or volume within the wind tunnel test section at, along, or within which probes are calibrated. At a particular wind tunnel velocity setting, the average velocity pressures at specified points at, along, or within the calibration location shall vary by no more than 2 percent or 0.3 mm  $H_2O$  (0.01 in.  $H_2O$ ), whichever is less restrictive, from the average velocity pressure at the calibration pitot tube location. Air flow at this location shall be axial, i.e., yaw and pitch angles within ±° of 0°. Compliance with these flow criteria shall be demonstrated by performing the procedures prescribed in sections 10.1.1 and 10.1.2. For circular tunnels, no part of the calibration location may be closer to the tunnel wall than 10.2 cm (4 in.) or 25 percent of the tunnel diameter, whichever is farther from the wall. For elliptical or rectangular tunnels, no part of the calibration location may be closer to the tunnel wall than 10.2 cm (4 in.) or 25 percent of the applicable cross-sectional axis, whichever is farther from the wall.

3.21 Wind Tunnel with Documented Axial Flow. A wind tunnel facility documented as meeting the provisions of sections 10.1.1 (velocity pressure crosscheck) and 10.1.2 (axial flow verification) using the procedures described in these sections or alternative procedures determined to be technically equivalent.

3.22 Yaw Angle. The angle between the axis of the stack or duct and the yaw component of flow, i.e., the component of the total velocity vector in a plane perpendicular to the traverse line at a particular traverse point. (Figure 2F-1 illustrates the "yaw plane.") From the standpoint of a tester facing a test port in a vertical stack, the yaw component of flow is the vector of flow moving to the left or right from the center of the stack as viewed by the tester. (This is sometimes referred to as "vortex flow," i.e., flow around the centerline of a stack or duct.) The yaw angle is the angle described by this yaw component of flow and the vertical axis of the stack. The algebraic sign convention is illustrated in Figure 2F-2.

3.23 Yaw Nulling. A procedure in which a probe is rotated about its axis in a stack or duct until a zero differential pressure reading ("yaw null") is obtained. When a 3–D probe is yaw-nulled, its impact pressure port ( $P_1$ ) faces directly into the direction of flow in the stack or duct and the differential pressure between pressure ports  $P_2$  and  $P_3$  is zero.

- 4.0 Interferences. [Reserved]
- 5.0 Safety.

5.1 This test method may involve hazardous operations and the use of hazardous materials or equipment. This method does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to establish and implement appropriate safety and health practices and to determine the applicability of regulatory limitations before using this test method.

#### 6.0 Equipment and Supplies

6.1 Three-dimensional Probes. The 3–D probes as specified in subsections 6.1.1

through 6.1.3 below qualify for use based on comprehensive wind tunnel and field studies involving both inter-and intra-probe comparisons by multiple test teams. Other types of probes shall not be used unless approved by the Administrator. Each 3-D probe shall have a unique identification number or code permanently marked on the main probe sheath. The minimum recommended diameter of the sensing head of any probe used under this method is 2.5 cm (1 in.). Each probe shall be calibrated prior to use according to the procedures in section 10. Manufacturer-supplied calibration data shall be used as example information only, except when the manufacturer calibrates the 3-D probe as specified in section 10 and provides complete documentation.

6.1.1 Five-hole prism-shaped probe. This type of probe consists of five pressure taps in the flat facets of a prism-shaped sensing head. The pressure taps are numbered 1 through 5, with the pressures measured at each hole referred to as P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>, P<sub>4</sub>, and P<sub>5</sub>, respectively. Figure 2F-3 is an illustration of the placement of pressure taps on a commonly available five-hole prism-shaped probe, the 2.5-cm (1-in.) DAT probe. (Note: Mention of trade names or specific products does not constitute endorsement by the U.S. Environmental Protection Agency.) The numbering arrangement for the prism-shaped sensing head presented in Figure 2F-3 shall be followed for correct operation of the probe. A brief description of the probe measurements involved is as follows: the differential pressure P2-P3 is used to yaw null the probe and determine the yaw angle; the differential pressure  $P_4$ - $P_5$  is a function of pitch angle; and the differential pressure  $P_1$ – $P_2$  is a function of total velocity

6.1.2 Five-hole spherical probe. This type of probe consists of five pressure taps in a spherical sensing head. As with the prismshaped probe, the pressure taps are numbered 1 through 5, with the pressures measured at each hole referred to as P<sub>1</sub>, P<sub>2</sub> P<sub>3</sub>, P<sub>4</sub>, and P<sub>5</sub>, respectively. However, the P<sub>4</sub> and P<sub>5</sub> pressure taps are in the reverse location from their respective positions on the prism-shaped probe head. The differential pressure P<sub>2</sub>–P<sub>3</sub> is used to yaw null the probe and determine the yaw angle; the differential pressure  $P_4$ – $P_5$  is a function of pitch angle; and the differential pressure  $P_1 - P_2$  is a function of total velocity. A diagram of a typical spherical probe sensing head is presented in Figure 2F-4. Typical probe dimensions are indicated in the illustration.

6.1.3 A manual 3–D probe refers to a fivehole prism-shaped or spherical probe that is positioned at individual traverse points and yaw nulled manually by an operator. An automated 3–D probe refers to a system that uses a computer-controlled motorized mechanism to position the five-hole prismshaped or spherical head at individual traverse points and perform yaw angle determinations.

6.1.4 Other three-dimensional probes. [Reserved]

6.1.5 Probe sheath. The probe shaft shall include an outer sheath to: (1) provide a surface for inscribing a permanent reference

scribe line, (2) accommodate attachment of an angle-measuring device to the probe shaft, and (3) facilitate precise rotational movement of the probe for determining yaw angles. The sheath shall be rigidly attached to the probe assembly and shall enclose all pressure lines from the probe head to the farthest position away from the probe head where an anglemeasuring device may be attached during use in the field. The sheath of the fully assembled probe shall be sufficiently rigid and straight at all rotational positions such that, when one end of the probe shaft is held in a horizontal position, the fully extended probe meets the horizontal straightness specifications indicated in section 8.2 below.

6.1.6 Scribe lines.

6.1.6.1 Reference scribe line. A permanent line, no greater than 1.6 mm (1/ 16 in.) in width, shall be inscribed on each manual probe that will be used to determine yaw angles of flow. This line shall be placed on the main probe sheath in accordance with the procedures described in section 10.4 and is used as a reference position for installation of the yaw angle-measuring device on the probe. At the discretion of the tester, the scribe line may be a single line segment placed at a particular position on the probe sheath (e.g., near the probe head), multiple line segments placed at various locations along the length of the probe sheath (e.g., at every position where a yaw angle-measuring device may be mounted), or a single continuous line extending along the full length of the probe sheath.

6.1.6.2 Scribe line on probe extensions. A permanent line may also be inscribed on any probe extension that will be attached to the main probe in performing field testing. This allows a yaw angle-measuring device mounted on the extension to be readily aligned with the reference scribe line on the main probe sheath.

6.1.6.3 Alignment specifications. This specification shall be met separately, using the procedures in section 10.4.1, on the main probe and on each probe extension. The rotational position of the scribe line or scribe line segments on the main probe or any probe extension must not vary by more than  $2^{\circ}$ . That is, the difference between the minimum and maximum of all of the rotational angles that are measured along the full length of the main probe or the probe extension must not exceed  $2^{\circ}$ .

6.1.7 Probe and system characteristics to ensure horizontal stability.

6.1.7.1 For manual probes, it is recommended that the effective length of the probe (coupled with a probe extension, if necessary) be at least 0.9 m (3 ft.) longer than the farthest traverse point mark on the probe shaft away from the probe head. The operator should maintain the probe's horizontal stability when it is fully inserted into the stack or duct. If a shorter probe is used, the probe should be inserted through a bushing sleeve, similar to the one shown in Figure 2F-5, that is installed on the test port; such a bushing shall fit snugly around the probe and be secured to the stack or duct entry port in such a manner as to maintain the probe's horizontal stability when fully inserted into the stack or duct.

6.1.7.2 An automated system that includes an external probe casing with a

transport system shall have a mechanism for maintaining horizontal stability comparable to that obtained by manual probes following the provisions of this method. The automated probe assembly shall also be constructed to maintain the alignment and position of the pressure ports during sampling at each traverse point. The design of the probe casing and transport system shall allow the probe to be removed from the stack or duct and checked through direct physical measurement for angular position and insertion depth.

6.1.8 The tubing that is used to connect the probe and the pressure-measuring device should have an inside diameter of at least 3.2 mm (1/8 in.), to reduce the time required for pressure equilibration, and should be as short as practicable.

6.2 Yaw Angle-measuring Device. One of the following devices shall be used for measurement of the yaw angle of flow.

6.2.1 Digital inclinometer. This refers to a digital device capable of measuring and displaying the rotational position of the probe to within  $\pm 1^{\circ}$ . The device shall be able to be locked into position on the probe sheath or probe extension, so that it indicates the probe's rotational position throughout the test. A rotational position collar block that can be attached to the probe sheath (similar to the collar shown in Figure 2F–6) may be required to lock the digital inclinometer into position on the probe sheath.

6.2.2 Protractor wheel and pointer assembly. This apparatus, similar to that shown in Figure 2F–7, consists of the following components.

6.2.2.1 A protractor wheel that can be attached to a port opening and set in a fixed rotational position to indicate the yaw angle position of the probe's scribe line relative to the longitudinal axis of the stack or duct. The protractor wheel must have a measurement ring on its face that is no less than 17.8 cm (7 in.) in diameter, shall be able to be rotated to any angle and then locked into position on the stack or duct port, and shall indicate angles to a resolution of 1°.

6.2.2.2 A pointer assembly that includes an indicator needle mounted on a collar that can slide over the probe sheath and be locked into a fixed rotational position on the probe sheath. The pointer needle shall be of sufficient length, rigidity, and sharpness to allow the tester to determine the probe's angular position to within 1° from the markings on the protractor wheel. Corresponding to the position of the pointer, the collar must have a scribe line to be used in aligning the pointer with the scribe line on the probe sheath.

6.2.3 Other yaw angle-measuring devices. Other angle-measuring devices with a manufacturer's specified precision of 1° or better may be used, if approved by the Administrator.

6.3 Probe Supports and Stabilization Devices. When probes are used for determining flow angles, the probe head should be kept in a stable horizontal position. For probes longer than 3.0 m (10 ft.), the section of the probe that extends outside the test port shall be secured. Three alternative devices are suggested for maintaining the horizontal position and

stability of the probe shaft during flow angle determinations and velocity pressure measurements: (1) Monorails installed above each port, (2) probe stands on which the probe shaft may be rested, or (3) bushing sleeves of sufficient length secured to the test ports to maintain probes in a horizontal position. Comparable provisions shall be made to ensure that automated systems maintain the horizontal position of the probe in the stack or duct. The physical characteristics of each test platform may dictate the most suitable type of stabilization device. Thus, the choice of a specific stabilization device is left to the judgment of the testers.

6.4 Differential Pressure Gauges. The pressure ( $\Delta P$ ) measuring devices used during wind tunnel calibrations and field testing shall be either electronic manometers (e.g., pressure transducers), fluid manometers, or mechanical pressure gauges (e.g., Magnehelic<sup>®</sup> gauges). Use of electronic manometers is recommended. Under low velocity conditions, use of electronic manometers may be necessary to obtain acceptable measurements.

6.4.1 Differential pressure-measuring device. This refers to a device capable of measuring pressure differentials and having a readability of  $\pm 1$  percent of full scale. The device shall be capable of accurately measuring the maximum expected pressure differential. Such devices are used to determine the following pressure measurements: velocity pressure, static pressure, yaw-null pressure, and pitch-angle pressure. For an inclined-vertical manometer, the readability specification of ±1 percent shall be met separately using the respective full-scale upper limits of the inclined and vertical portions of the scales. To the extent practicable, the device shall be selected such that most of the pressure readings are between 10 and 90 percent of the device's full-scale measurement range (as defined in section 3.5). Typical velocity pressure ( $P_1$ – $P_2$ ranges for both the prism-shaped probe and the spherical probe are 0 to 1.3 cm H<sub>2</sub>O (0 to 0.5 in. H<sub>2</sub>O), 0 to 5.1 cm H<sub>2</sub>O (0 to 2 in. H<sub>2</sub>O), and 0 to 12.7 cm H<sub>2</sub>O (0 to 5 in. H<sub>2</sub>O). The pitch angle  $(P_4-P_5)$  pressure range is typically -6.4 to +6.4 mm H<sub>2</sub>O (-0.25 to +0.25 in. H<sub>2</sub>O) or -12.7 to +12.7 mm H<sub>2</sub>O  $(-0.5 \text{ to } +0.5 \text{ in. } H_2\text{O})$  for the prism-shaped probe, and -12.7 to +12.7 mm H<sub>2</sub>O (-0.5 to +0.5 in. H<sub>2</sub>O) or -5.1 to +5.1 cm H<sub>2</sub>O (-2to +2 in.  $H_2O$ ) for the spherical probe. The pressure range for the yaw null  $(P_2-P_3)$ readings is typically -12.7 to +12.7 mm H<sub>2</sub>O  $(-0.5 \text{ to } +0.5 \text{ in. } \text{H}_2\text{O})$  for both probe types In addition, pressure-measuring devices should be selected such that the zero does not drift by more than 5 percent of the average expected pressure readings to be encountered during the field test. This is particularly important under low pressure conditions.

6.4.2 Gauge used for yaw nulling. The differential pressure-measuring device chosen for yaw nulling the probe during the wind tunnel calibrations and field testing shall be bi-directional, i.e., capable of reading both positive and negative differential pressures. If a mechanical, bi-directional pressure gauge is chosen, it shall have a full-

scale range no greater than 2.6 cm  $H_2O$  (1 in.  $H_2O)$  [i.e., -1.3 to +1.3 cm  $H_2O$  (-0.5 in. to +0.5 in.)].

6.4.3 Devices for calibrating differential pressure-measuring devices. A precision manometer (e.g., a U-tube, inclined, or inclined-vertical manometer, or micromanometer) or NIST (National Institute of Standards and Technology) traceable pressure source shall be used for calibrating differential pressure-measuring devices. The device shall be maintained under laboratory conditions or in a similar protected environment (e.g., a climate-controlled trailer). It shall not be used in field tests. The precision manometer shall have a scale gradation of 0.3 mm  $H_2O$  (0.01 in.  $H_2O$ ), or less, in the range of 0 to 5.1 cm  $H_2O$  (0 to 2 in. H<sub>2</sub>O) and 2.5 mm H<sub>2</sub>O (0.1 in. H<sub>2</sub>O), or less, in the range of 5.1 to 25.4 cm  $H_2O$  (2 to 10 in. H<sub>2</sub>O). The manometer shall have manufacturer's documentation that it meets an accuracy specification of at least 0.5 percent of full scale. The NIST-traceable pressure source shall be recertified annually.

6.4.4 Devices used for post-test calibration check. A precision manometer meeting the specifications in section 6.4.3, a pressure-measuring device or pressure source with a documented calibration traceable to NIST, or an equivalent device approved by the Administrator shall be used for the posttest calibration check. The pressuremeasuring device shall have a readability equivalent to or greater than the tested device. The pressure source shall be capable of generating pressures between 50 and 90 percent of the range of the tested device and known to within  $\pm 1$  percent of the full scale of the tested device. The pressure source shall be recertified annually.

6.5 Data Display and Capture Devices. Electronic manometers (if used) shall be coupled with a data display device (such as a digital panel meter, personal computer display, or strip chart) that allows the tester to observe and validate the pressure measurements taken during testing. They shall also be connected to a data recorder (such as a data logger or a personal computer with data capture software) that has the ability to compute and retain the appropriate average value at each traverse point, identified by collection time and traverse point.

6.6 Temperature Gauges. For field tests, a thermocouple or resistance temperature detector (RTD) capable of measuring temperature to within  $\pm 3^{\circ}$ C ( $\pm 5^{\circ}$ F) of the stack or duct temperature shall be used. The thermocouple shall be attached to the probe such that the sensor tip does not touch any metal and is located on the opposite side of the probe head from the pressure ports so as not to interfere with the gas flow around the probe head. The position of the thermocouple relative to the pressure port face openings shall be in the same configuration as used for the probe calibrations in the wind tunnel. Temperature gauges used for wind tunnel calibrations shall be capable of measuring temperature to within  $\pm 0.6^{\circ}$ C ( $\pm 1^{\circ}$ F) of the temperature of the flowing gas stream in the wind tunnel.

6.7 Stack or Duct Static Pressure Measurement. The pressure-measuring device used with the probe shall be as specified in section 6.4 of this method. The static tap of a standard (Prandtl type) pitot tube or one leg of a Type S pitot tube with the face opening planes positioned parallel to the gas flow may be used for this measurement. Also acceptable is the pressure differential reading of P<sub>1</sub>-P<sub>bar</sub> from a five-hole prism-shaped probe (e.g., Type DA or DAT probe) with the P1 pressure port face opening positioned parallel to the gas flow in the same manner as the Type S probe. However, the spherical probe, as specified in section 6.1.2, is unable to provide this measurement and shall not be used to take static pressure measurements. Static pressure measurement is further described in section 8.11.

6.8 Barometer. Same as Method 2, section 2.5.

6.9 Gas Density Determination Equipment. Method 3 or 3A shall be used to determine the dry molecular weight of the stack gas. Method 4 shall be used for moisture content determination and computation of stack gas wet molecular weight. Other methods may be used, if approved by the Administrator.

6.10 Calibration Pitot Tube. Same as Method 2, section 2.7.

6.11 Wind Tunnel for Probe Calibration. Wind tunnels used to calibrate velocity probes must meet the following design specifications.

6.11.1 Test section cross-sectional area. The flowing gas stream shall be confined within a circular, rectangular, or elliptical duct. The cross-sectional area of the tunnel must be large enough to ensure fully developed flow in the presence of both the calibration pitot tube and the tested probe. The calibration site, or "test section," of the wind tunnel shall have a minimum diameter of 30.5 cm (12 in.) for circular or elliptical duct cross-sections or a minimum width of 30.5 cm (12 in.) on the shorter side for rectangular cross-sections. Wind tunnels shall meet the probe blockage provisions of this section and the qualification requirements prescribed in section 10.1. The projected area of the portion of the probe head, shaft, and attached devices inside the wind tunnel during calibration shall represent no more than 4 percent of the cross-sectional area of the tunnel. The projected area shall include the combined area of the calibration pitot tube and the tested probe if both probes are placed simultaneously in the same cross-sectional plane in the wind tunnel, or the larger projected area of the two probes if they are placed alternately in the wind tunnel.

6.11.2 Velocity range and stability. The wind tunnel should be capable of maintaining velocities between 6.1 m/sec and 30.5 m/sec (20 ft/sec and 100 ft/sec). The wind tunnel shall produce fully developed flow patterns that are stable and parallel to the axis of the duct in the test section.

6.11.3 Flow profile at the calibration location. The wind tunnel shall provide axial flow within the test section calibration location (as defined in section 3.20). Yaw and pitch angles in the calibration location shall be within  $\pm 3^{\circ}$  of 0°. The procedure for determining that this requirement has been met is described in section 10.1.2.

6.11.4 Entry ports in the wind tunnel test section.

6.11.4.1 Port for tested probe. A port shall be constructed for the tested probe. The port should have an elongated slot parallel to the axis of the duct at the test section. The elongated slot should be of sufficient length to allow attaining all the pitch angles at which the probe will be calibrated for use in the field. To facilitate alignment of the probe during calibration, the test section should include a window constructed of a transparent material to allow the tested probe to be viewed. This port shall be located to allow the head of the tested probe to be positioned within the calibration location (as defined in section 3.20) at all pitch angle settings.

6.11.4.2 Port for verification of axial flow. Depending on the equipment selected to conduct the axial flow verification prescribed in section 10.1.2, a second port, located  $90^{\circ}$  from the entry port for the tested probe, may be needed to allow verification that the gas flow is parallel to the central axis of the test section. This port should be located and constructed so as to allow one of the probes described in section 10.1.2.2 to access the same test point(s) that are accessible from the port described in section 6.11.4.1.

6.11.4.3 Port for calibration pitot tube. The calibration pitot tube shall be used in the port for the tested probe or a separate entry port. In either case, all measurements with the calibration pitot tube shall be made at the same point within the wind tunnel over the course of a probe calibration. The measurement point for the calibration pitot tube shall meet the same specifications for distance from the wall and for axial flow as described in section 3.20 for the wind tunnel calibration location.

6.11.5 Pitch angle protractor plate. A protractor plate shall be attached directly under the port used with the tested probe and set in a fixed position to indicate the pitch angle position of the probe relative to the longitudinal axis of the wind tunnel duct (similar to Figure 2F-8). The protractor plate shall indicate angles in 5° increments with a minimum resolution of  $\pm 2^{\circ}$ . The tested probe shall be able to be locked into position at the desired pitch angle delineated on the protractor. The probe head position shall be maintained within the calibration location (as defined in section 3.20) in the test section of the wind tunnel during all tests across the range of pitch angles.

#### 7.0 Reagents and Standards. [Reserved]

#### 8.0 Sample Collection and Analysis

#### 8.1 Equipment Inspection and Set-Up

8.1.1 All probes, differential pressuremeasuring devices, yaw angle-measuring devices, thermocouples, and barometers shall have a current, valid calibration before being used in a field test. (See sections 10.3.3, 10.3.4, and 10.5 through10.10 for the applicable calibration requirements.)

8.1.2 Before each field use of a 3-D probe, perform a visual inspection to verify the physical condition of the probe head according to the procedures in section 10.2. Record the inspection results on a form similar to Table 2F–1. If there is visible damage to the 3-D probe, the probe shall not be used until it is recalibrated.

8.1.3 After verifying that the physical condition of the probe head is acceptable, set up the apparatus using lengths of flexible tubing that are as short as practicable. Surge tanks installed between the probe and pressure-measuring device may be used to dampen pressure fluctuations provided that an adequate measurement response time (see section 8.8) is maintained.

8.2 Horizontal Straightness Check. A horizontal straightness check shall be performed before the start of each field test, except as otherwise specified in this section. Secure the fully assembled probe (including the probe head and all probe shaft extensions) in a horizontal position using a stationary support at a point along the probe shaft approximating the location of the stack or duct entry port when the probe is sampling at the farthest traverse point from the stack or duct wall. The probe shall be rotated to detect bends. Use an anglemeasuring device or trigonometry to determine the bend or sag between the probe head and the secured end. (See Figure 2F 9.) Probes that are bent or sag by more than 5° shall not be used. Although this check does not apply when the probe is used for a vertical traverse, care should be taken to avoid the use of bent probes when conducting vertical traverses. If the probe is constructed of a rigid steel material and consists of a main probe without probe extensions, this check need only be performed before the initial field use of the probe, when the probe is recalibrated, when a change is made to the the design or material of the probe assembly, and when the probe becomes bent. With such probes, a visual inspection shall be made of the fully assembled probe before each field test to determine if a bend is visible. The probe shall be rotated to detect bends. The inspection results shall be documented in the field test report. If a bend in the probe is visible, the horizontal straightness check shall be performed before the probe is used.

8.3 Rotational Position Check. Before each field test, and each time an extension is added to the probe during a field test, a rotational position check shall be performed on all manually operated probes (except as noted in section 8.3.5, below) to ensure that, throughout testing, the angle-measuring device is either: aligned to within  $\pm 1^{\circ}$  of the rotational position of the reference scribe line; or is affixed to the probe such that the rotational offset of the device from the reference scribe line is known to within  $\pm 1^{\circ}$ . This check shall consist of direct measurements of the rotational positions of the reference scribe line and angle-measuring device sufficient to verify that these specifications are met. Annex A in section 18 of this method gives recommended procedures for performing the rotational position check, and Table 2F-2 gives an example data form. Procedures other than those recommended in Annex A in section 18 may be used, provided they demonstrate whether the alignment specification is met and are explained in detail in the field test report.

8.3.1 Angle-measuring device rotational offset. The tester shall maintain a record of

the angle-measuring device rotational offset,  $R_{\rm ADO}$ , as defined in section 3.1. Note that  $R_{\rm ADO}$  is assigned a value of 0° when the angle-measuring device is aligned to within  $\pm 1^\circ$  of the rotational position of the reference scribe line. The  $R_{\rm ADO}$  shall be used to determine the yaw angle of flow in accordance with section 8.9.4.

8.3.2 Sign of angle-measuring device rotational offset. The sign of  $R_{\rm ADO}$  is positive when the angle-measuring device (as viewed from the "tail" end of the probe) is positioned in a clockwise direction from the reference scribe line and negative when the device is positioned in a counterclockwise direction from the reference scribe line.

8.3.3 Angle-measuring devices that can be independently adjusted (e.g., by means of a set screw), after being locked into position on the probe sheath, may be used. However, the  $R_{ADO}$  must also take into account this adjustment.

8.3.4 Post-test check. If probe extensions remain attached to the main probe throughout the field test, the rotational position check shall be repeated, at a minimum, at the completion of the field test to ensure that the angle-measuring device has remained within ±2° of its rotational position established prior to testing. At the discretion of the tester, additional checks may be conducted after completion of testing at any sample port or after any test run. If the  $\pm 2$ specification is not met, all measurements made since the last successful rotational position check must be repeated. Section 18.1.1.3 of Annex A provides an example procedure for performing the post-test check. 8.3.5 Exceptions.

8.3.5.1 A rotational position check need

not be performed if, for measurements taken at all velocity traverse points, the yaw anglemeasuring device is mounted and aligned directly on the reference scribe line specified in sections 6.1.6.1 and 6.1.6.3 and no independent adjustments, as described in section 8.3.3, are made to the device's rotational position.

8.3.5.2 If extensions are detached and reattached to the probe during a field test, a rotational position check need only be performed the first time an extension is added to the probe, rather than each time the extension is re-attached, if the probe extension is designed to be locked into a mechanically fixed rotational position (e.g., through use of interlocking grooves) that can re-establish the initial rotational position to within  $\pm 1^{\circ}$ .

8.4 Leak Checks. A pre-test leak check shall be conducted before each field test. A post-test check shall be performed at the end of the field test, but additional leak checks may be conducted after any test run or group of test runs. The post-test check may also serve as the pre-test check for the next group of test runs. If any leak check is failed, all runs since the last passed leak check are invalid. While performing the leak check procedures, also check each pressure device's responsiveness to the changes in pressure.

8.4.1 To perform the leak check, pressurize the probe's  $P_1$  pressure port until at least 7.6 cm  $H_2O$  (3 in.  $H_2O$ ) pressure, or a pressure corresponding to approximately 75 percent of the pressure-measuring device's measurement scale, whichever is less, registers on the device; then, close off the pressure port. The pressure shall remain stable [ $\pm 2.5$  mm H<sub>2</sub>O ( $\pm 0.10$  in. H<sub>2</sub>O)] for at least 15 seconds. Check the P<sub>2</sub>, P<sub>3</sub>, P<sub>4</sub>, and P<sub>5</sub> pressure ports in the same fashion. Other leak-check procedures may be used, if approved by the Administrator.

8.5 Zeroing the Differential Pressuremeasuring Device. Zero each differential pressure-measuring device, including the device used for yaw nulling, before each field test. At a minimum, check the zero after each field test. A zero check may also be performed after any test run or group of test runs. For fluid manometers and mechanical pressure gauges (e.g., Magnehelic® gauges), the zero reading shall not deviate from zero by more than  $\pm 0.8$  mm H<sub>2</sub>O ( $\pm 0.03$  in. H<sub>2</sub>O) or one minor scale division, whichever is greater, between checks. For electronic manometers, the zero reading shall not deviate from zero between checks by more than:  $\pm 0.3 \text{ mm H}_2\text{O}$  ( $\pm 0.01 \text{ in. H}_2\text{O}$ ), for full scales less than or equal to 5.1 cm H<sub>2</sub>O (2.0 in.  $H_2O$ ); or ±0.8 mm  $H_2O$  (±0.03 in.  $H_2O$ ), for full scales greater than 5.1 cm H<sub>2</sub>O (2.0 in. H<sub>2</sub>O). (Note: If negative zero drift is not directly readable, estimate the reading based on the position of the gauge oil in the manometer or of the needle on the pressure gauge.) In addition, for all pressuremeasuring devices except those used exclusively for yaw nulling, the zero reading shall not deviate from zero by more than 5 percent of the average measured differential pressure at any distinct process condition or load level. If any zero check is failed at a specific process condition or load level, all runs conducted at that process condition or load level since the last passed zero check are invalid.

8.6 Traverse Point Verification. The number and location of the traverse points shall be selected based on Method 1 guidelines. The stack or duct diameter and port nipple lengths, including any extension of the port nipples into stack or duct, shall be verified the first time the test is performed; retain and use this information for subsequent field tests, updating it as required. Physically measure the stack or duct dimensions or use a calibrated laser device; do not use engineering drawings of the stack or duct. The probe length necessary to reach each traverse point shall be recorded to within  $\pm 6.4$  mm ( $\pm 1/4$  in.) and, for manual probes, marked on the probe sheath. In determining these lengths, the tester shall take into account both the distance that the port flange projects outside of the stack and the depth that any port nipple extends into the gas stream. The resulting point positions shall reflect the true distances from the inside wall of the stack or duct, so that when the tester aligns any of the markings with the outside face of the stack port, the probe's impact port shall be located at the appropriate distance from the inside wall for the respective Method 1 traverse point. Before beginning testing at a particular location, an out-of-stack or duct verification shall be performed on each probe that will be used to ensure that these position markings are correct. The distances measured during the verification must agree with the

previously calculated distances to within  $\pm 1/4$  in. For manual probes, the traverse point positions shall be verified by measuring the distance of each mark from the probe's P<sub>1</sub> pressure port. A comparable out-of-stack test shall be performed on automated probe systems. The probe shall be extended to each of the prescribed traverse point positions. Then, the accuracy of the positioning for each traverse point shall be verified by measuring the distance between the port flange and the probe's P<sub>1</sub> pressure port.

8.7 Probe Installation. Insert the probe into the test port. A solid material shall be used to seal the port.

8.8 System Response Time. Determine the response time of the probe measurement system. Insert and position the "cold" probe (at ambient temperature and pressure) at any Method 1 traverse point. Read and record the probe's  $P_1$ – $P_2$  differential pressure, temperature, and elapsed time at 15-second intervals until stable readings for both pressure and temperature are achieved. The response time is the longer of these two elapsed times. Record the response time. 8.9 Sampling.

8.9.1 Yaw angle measurement protocol. With manual probes, yaw angle measurements may be obtained in two alternative ways during the field test, either by using a yaw angle-measuring device (e.g., digital inclinometer) affixed to the probe, or using a protractor wheel and pointer assembly. For horizontal traversing, either approach may be used. For vertical traversing, i.e., when measuring from on top or into the bottom of a horizontal duct, only the protractor wheel and pointer assembly may be used. With automated probes, curvefitting protocols may be used to obtain yawangle measurements.

8.9.1.1 If a yaw angle-measuring device affixed to the probe is to be used, lock the device on the probe sheath, aligning it either on the reference scribe line or in the rotational offset position established under section 8.3.1.

**8.9.1.2** If a protractor wheel and pointer assembly is to be used, follow the procedures in Annex B of this method.

8.9.1.3 Other yaw angle-determination procedures. If approved by the Administrator, other procedures for determining yaw angle may be used, provided that they are verified in a wind tunnel to be able to perform the yaw angle calibration procedure as described in section 10.5.

8.9.2 Sampling strategy. At each traverse point, first yaw-null the probe, as described in section 8.9.3, below. Then, with the probe oriented into the direction of flow, measure and record the yaw angle, the differential pressures and the temperature at the traverse point, after stable readings are achieved, in accordance with sections 8.9.4 and 8.9.5. At the start of testing in each port (i.e., after a probe has been inserted into the flue gas stream), allow at least the response time to elapse before beginning to take measurements at the first traverse point accessed from that port. Provided that the probe is not removed from the flue gas stream, measurements may be taken at subsequent traverse points accessed from the

same test port without waiting again for the response time to elapse.

8.9.3 Yaw-nulling procedure. In preparation for yaw angle determination, the probe must first be yaw nulled. After positioning the probe at the appropriate traverse point, perform the following procedures.

8.9.3.1 Rotate the probe until a null differential pressure reading (the difference in pressures across the  $P_2$  and  $P_3$  pressure ports is zero, i.e.,  $P_2 = P_3$ ) is indicated by the yaw angle pressure gauge. Read and record the angle displayed by the angle-measuring device.

8.9.3.2 Sign of the measured angle. The angle displayed on the angle-measuring device is considered positive when the probe's impact pressure port (as viewed from the "tail" end of the probe) is oriented in a clockwise rotational position relative to the stack or duct axis and is considered negative when the probe's impact pressure port is oriented in a counterclockwise rotational position (see Figure 2F–10).

8.9.4 Yaw angle determination. After performing the yaw-nulling procedure in section 8.9.3, determine the yaw angle of flow according to one of the following procedures. Special care must be observed to take into account the signs of the recorded angle and all offsets.

8.9.4.1 Direct-reading. If all rotational offsets are zero or if the angle-measuring device rotational offset ( $R_{ADO}$ ) determined in section 8.3 exactly compensates for the scribe line rotational offset ( $R_{SLO}$ ) determined in section 10.5, then the magnitude of the yaw angle is equal to the displayed angle-measuring device reading from section 8.9.3.1. The algebraic sign of the yaw angle is determined in accordance with section 8.9.3.2.

**Note**: Under certain circumstances (e.g., testing of horizontal ducts), a 90° adjustment to the angle-measuring device readings may be necessary to obtain the correct yaw angles.

8.9.4.2 Compensation for rotational offsets during data reduction. When the angle-measuring device rotational offset does not compensate for reference scribe line rotational offset, the following procedure shall be used to determine the yaw angle:

(a) Enter the reading indicated by the angle-measuring device from section 8.9.3.1.(b) Associate the proper algebraic sign from

section 8.9.3.2 with the reading in step (a). (c) Subtract the reference scribe line

rotational offset,  $R_{SLO}$ , from the reading in step (b).

(d) Subtract the angle-measuring device rotational offset,  $R_{\rm ADO}$ , if any, from the result obtained in step (c).

(e) The final result obtained in step (d) is the yaw angle of flow.

**Note:** It may be necessary to first apply a 90° adjustment to the reading in step (a), in order to obtain the correct yaw angle.

8.9.4.3 Record the yaw angle measurements on a form similar to Table 2F–3.

8.9.5 Velocity determination. Maintain the probe rotational position established during the yaw angle determination. Then, begin recording the pressure-measuring

device readings for the impact pressure (P1- $P_2$ ) and pitch angle pressure ( $P_4$ - $P_5$ ). These pressure measurements shall be taken over a sampling period of sufficiently long duration to ensure representative readings at each traverse point. If the pressure measurements are determined from visual readings of the pressure device or display, allow sufficient time to observe the pulsation in the readings to obtain a sight-weighted average, which is then recorded manually. If an automated data acquisition system (e.g., data logger, computer-based data recorder, strip chart recorder) is used to record the pressure measurements, obtain an integrated average of all pressure readings at the traverse point. Stack or duct gas temperature measurements shall be recorded, at a minimum, once at each traverse point. Record all necessary data as shown in the example field data form (Table 2F-3).

8.9.6 Alignment check. For manually operated probes, after the required yaw angle and differential pressure and temperature measurements have been made at each traverse point, verify (e.g., by visual inspection) that the yaw angle-measuring device has remained in proper alignment with the reference scribe line or with the rotational offset position established in section 8.3. If, for a particular traverse point, the angle-measuring device is found to be in proper alignment, proceed to the next traverse point; otherwise, re-align the device and repeat the angle and differential pressure measurements at the traverse point. In the course of a traverse, if a mark used to properly align the angle-measuring device (e.g., as described in section 18.1.1.1) cannot be located, re-establish the alignment mark before proceeding with the traverse

8.10 Probe Plugging. Periodically check for plugging of the pressure ports by observing the responses on pressure differential readouts. Plugging causes erratic results or sluggish responses. Rotate the probe to determine whether the readouts respond in the expected direction. If plugging is detected, correct the problem and repeat the affected measurements.

8.11 Static Pressure. Measure the static pressure in the stack or duct using the equipment described in section 6.7.

8.11.1 If a Type DA or DAT probe is used for this measurement, position the probe at or between any traverse point(s) and rotate the probe until a null differential pressure reading is obtained at  $P_2$ – $P_3$ . Rotate the probe 90°. Disconnect the  $P_2$  pressure side of the probe and read the pressure  $P_1$ - $P_{bar}$  and record as the static pressure. (**Note**: The spherical probe, specified in section 6.1.2, is unable to provide this measurement and shall not be used to take static pressure measurements.)

8.11.2 If a Type S probe is used for this measurement, position the probe at or between any traverse point(s) and rotate the probe until a null differential pressure reading is obtained. Disconnect the tubing from one of the pressure ports; read and record the  $\Delta P$ . For pressure devices with one-directional scales, if a deflection in the positive direction is noted with the negative side disconnected, then the static pressure is positive. Likewise, if a deflection in the

positive direction is noted with the positive side disconnected, then the static pressure is negative.

**8.12** Atmospheric Pressure. Determine the atmospheric pressure at the sampling elevation during each test run following the procedure described in section 2.5 of Method 2.

8.13 Molecular Weight. Determine the stack gas dry molecular weight. For combustion processes or processes that emit essentially  $CO_2$ ,  $O_2$ , CO, and  $N_2$ , use Method 3 or 3A. For processes emitting essentially air, an analysis need not be conducted; use a dry molecular weight of 29.0. Other methods may be used, if approved by the Administrator.

8.14 Moisture. Determine the moisture content of the stack gas using Method 4 or equivalent.

8.15 Data Recording and Calculations. Record all required data on a form similar to Table 2F–3.

8.15.1 Selection of appropriate calibration curves. Choose the appropriate pair of  $F_1$  and  $F_2$  versus pitch angle calibration curves, created as described in section 10.6.

8.15.2 Pitch angle derivation. Use the appropriate calculation procedures in section 12.2 to find the pitch angle ratios that are applicable at each traverse point. Then, find the pitch angles corresponding to these pitch angle ratios on the " $F_1$  versus pitch angle" curve for the probe.

8.15.3 Velocity calibration coefficient derivation. Use the pitch angle obtained following the procedures described in section 8.15.2 to find the corresponding velocity calibration coefficients from the " $F_2$  versus pitch angle" calibration curve for the probe. 8.15.4 Calculations. Calculate the axial

8.15.4 Calculations. Calculate the axial velocity at each traverse point using the equations presented in section 12.2 to account for the yaw and pitch angles of flow. Calculate the test run average stack gas velocity by finding the arithmetic average of the point velocity results in accordance with sections 12.3 and 12.4, and calculate the stack gas volumetric flow rate in accordance with section 12.5 or 12.6, as applicable.

#### 9.0 Quality Control

9.1 Quality Control Activities. In conjunction with the yaw angle determination and the pressure and temperature measurements specified in section 8.9, the following quality control checks should be performed.

9.1.1 Range of the differential pressure gauge. In accordance with the specifications in section 6.4, ensure that the proper differential pressure gauge is being used for the range of  $\pi$ P values encountered. If it is necessary to change to a more sensitive gauge, replace the gauge with a gauge calibrated according to section 10.3.3, perform the leak check described in section 8.4 and the zero check described in section 8.5, and repeat the differential pressure and temperature readings at each traverse point.

9.1.2 Horizontal stability check. For horizontal traverses of a stack or duct, visually check that the probe shaft is maintained in a horizontal position prior to taking a pressure reading. Periodically, during a test run, the probe's horizontal stability should be verified by placing a carpenter's level, a digital inclinometer, or other angle-measuring device on the portion of the probe sheath that extends outside of the test port. A comparable check should be performed by automated systems.

#### 10.0 Calibration

10.1 Wind Tunnel Qualification Checks. To qualify for use in calibrating probes, a wind tunnel shall have the design features specified in section 6.11 and satisfy the following qualification criteria. The velocity pressure cross-check in section 10.1.1 and axial flow verification in section 10.1.2 shall be performed before the initial use of the wind tunnel and repeated immediately after any alteration occurs in the wind tunnel's configuration, fans, interior surfaces, straightening vanes, controls, or other properties that could reasonably be expected to alter the flow pattern or velocity stability in the tunnel. The owner or operator of a wind tunnel used to calibrate probes according to this method shall maintain records documenting that the wind tunnel meets the requirements of sections 10.1.1 and 10.1.2 and shall provide these records to the Administrator upon request.

10.1.1 Velocity pressure cross-check. To verify that the wind tunnel produces the same velocity at the tested probe head as at the calibration pitot tube impact port, perform the following cross-check. Take three differential pressure measurements at the fixed calibration pitot tube location, using the calibration pitot tube specified in section 6.10, and take three measurements with the calibration pitot tube at the wind tunnel calibration location, as defined in section 3.20. Alternate the measurements between the two positions. Perform this procedure at the lowest and highest velocity settings at which the probes will be calibrated. Record the values on a form similar to Table 2F-4. At each velocity setting, the average velocity pressure obtained at the wind tunnel calibration location shall be within ±2 percent or 2.5 mm H<sub>2</sub>O (0.01 in. H<sub>2</sub>O), whichever is less restrictive, of the average velocity pressure obtained at the fixed calibration pitot tube location. This comparative check shall be performed at 2.5-cm (1-in.), or smaller, intervals across the full length, width, and depth (if applicable) of the wind tunnel calibration location. If the criteria are not met at every tested point, the wind tunnel calibration location must be redefined, so that acceptable results are obtained at every point. Include the results of the velocity pressure cross-check in the calibration data section of the field test report. (See section 16.1.4.)

10.1.2 Axial flow verification. The following procedures shall be performed to demonstrate that there is fully developed axial flow within the calibration location and at the calibration pitot tube location. Two testing options are available to conduct this check.

10.1.2.1 Using a calibrated 3–D probe. A 3–D probe that has been previously calibrated in a wind tunnel with documented axial flow (as defined in section 3.21) may be

used to conduct this check. Insert the calibrated 3-D probe into the wind tunnel test section using the tested probe port. Following the procedures in sections 8.9 and 12.2 of this method, determine the yaw and pitch angles at all the point(s) in the test section where the velocity pressure crosscheck, as specified in section 10.1.1, is performed. This includes all the points in the calibration location and the point where the calibration pitot tube will be located. Determine the yaw and pitch angles at each point. Repeat these measurements at the highest and lowest velocities at which the probes will be calibrated. Record the values on a form similar to Table 2F-5. Each measured yaw and pitch angle shall be within  $\pm 3^{\circ}$  of  $0^{\circ}$ . Exceeding the limits indicates unacceptable flow in the test section. Until the problem is corrected and acceptable flow is verified by repetition of this procedure, the wind tunnel shall not be used for calibration of probes. Include the results of the axial flow verification in the calibration data section of the field test report. (See section 16.1.4.)

10.1.2.2 Using alternative probes. Axial flow verification may be performed using an uncalibrated prism-shaped 3-D probe (e.g., DA or DAT probe) or an uncalibrated wedge probe. (Figure 2F-11 illustrates a typical wedge probe.) This approach requires use of two ports: the tested probe port and a second port located 90° from the tested probe port Each port shall provide access to all the points within the wind tunnel test section where the velocity pressure cross-check, as specified in section 10.1.1, is conducted. The probe setup shall include establishing a reference yaw-null position on the probe sheath to serve as the location for installing the angle-measuring device. Physical design features of the DA, DAT, and wedge probes are relied on to determine the reference position. For the DA or DAT probe, this reference position can be determined by setting a digital inclinometer on the flat facet where the P<sub>1</sub> pressure port is located and then identifying the rotational position on the probe sheath where a second anglemeasuring device would give the same angle reading. The reference position on a wedge probe shaft can be determined either geometrically or by placing a digital inclinometer on each side of the wedge and rotating the probe until equivalent readings are obtained. With the latter approach, the reference position is the rotational position on the probe sheath where an angle measuring device would give a reading of  $0^{\circ}$ . After installing the angle-measuring device in the reference yaw-null position on the probe sheath, determine the yaw angle from the tested port. Repeat this measurement using the 90° offset port, which provides the pitch angle of flow. Determine the yaw and pitch angles at all the point(s) in the test section where the velocity pressure cross-check, as specified in section 10.1.1, is performed. This includes all the points in the wind tunnel calibration location and the point where the calibration pitot tube will be located. Perform this check at the highest and lowest velocities at which the probes will be calibrated. Record the values on a form similar to Table 2F-5. Each measured yaw

and pitch angle shall be within  $\pm 3^{\circ}$  of  $0^{\circ}$ . Exceeding the limits indicates unacceptable flow in the test section. Until the problem is corrected and acceptable flow is verified by repetition of this procedure, the wind tunnel shall not be used for calibration of probes. Include the results in the probe calibration report.

10.1.3 Wind tunnel audits.

10.1.3.1 Procedure. Upon the request of the Administrator, the owner or operator of a wind tunnel shall calibrate a 3-D audit probe in accordance with the procedures described in sections 10.3 through 10.6. The calibration shall be performed at two velocities and over a pitch angle range that encompasses the velocities and pitch angles typically used for this method at the facility. The resulting calibration data and curves shall be submitted to the Agency in an audit test report. These results shall be compared by the Agency to reference calibrations of the audit probe at the same velocity and pitch angle settings obtained at two different wind tunnels.

10.1.3.2 Acceptance criteria. The audited tunnel's calibration is acceptable if all of the following conditions are satisfied at each velocity and pitch setting for the reference calibration obtained from at least one of the wind tunnels. For pitch angle settings between  $-15^{\circ}$  and  $+15^{\circ}$ , no velocity calibration coefficient (i.e., F2) may differ from the corresponding reference value by more than 3 percent. For pitch angle settings outside of this range (i.e., less than  $-15^{\circ}$  and greater than +15°), no velocity calibration coefficient may differ by more than 5 percent from the corresponding reference value. If the acceptance criteria are not met, the audited wind tunnel shall not be used to calibrate probes for use under this method until the problems are resolved and acceptable results are obtained upon completion of a subsequent audit.

10.2 Probe Inspection. Before each calibration of a 3-D probe, carefully examine the physical condition of the probe head. Particular attention shall be paid to the edges of the pressure ports and the surfaces surrounding these ports. Any dents, scratches, or asymmetries on the edges of the pressure ports and any scratches or indentations on the surfaces surrounding the pressure ports shall be noted because of the potential effect on the probe's pressure readings. If the probe has been previously calibrated, compare the current condition of the probe's pressure ports and surfaces to the results of the inspection performed during the probe's most recent wind tunnel calibration. Record the results of this inspection on a form and in diagrams similar to Table 2F-1. The information in Table 2F-1 will be used as the basis for comparison during the probe head inspections performed before each subsequent field use.

10.3 Pre-Calibration Procedures. Prior to calibration, a scribe line shall have been placed on the probe in accordance with section 10.4. The yaw angle and velocity calibration procedures shall not begin until the pre-test requirements in sections 10.3.1 through 10.3.4 have been met.

10.3.1 Perform the horizontal straightness check described in section 8.2 on the probe

assembly that will be calibrated in the wind tunnel.

10.3.2 Perform a leak check in accordance with section 8.4.

10.3.3 Except as noted in section 10.3.3.3, calibrate all differential pressure-measuring devices to be used in the probe calibrations, using the following procedures. At a minimum, calibrate these devices on each day that probe calibrations are performed.

10.3.3.1 Procedure. Before each wind tunnel use, all differential pressuremeasuring devices shall be calibrated against the reference device specified in section 6.4.3 using a common pressure source. Perform the calibration at three reference pressures representing 30, 60, and 90 percent of the full-scale range of the pressure-measuring device being calibrated. For an inclinedvertical manometer, perform separate calibrations on the inclined and vertical portions of the measurement scale, considering each portion of the scale to be a separate full-scale range. [For example, for a manometer with a 0- to 2.5-cm H<sub>2</sub>O (0- to 1in. H<sub>2</sub>O) inclined scale and a 2.5- to 12.7-cm H<sub>2</sub>O (1- to 5-in. H<sub>2</sub>O) vertical scale, calibrate the inclined portion at 7.6, 15.2, and 22.9 mm H<sub>2</sub>O (0.3, 0.6, and 0.9 in. H<sub>2</sub>O), and calibrate the vertical portion at 3.8, 7.6, and 11.4 cm H<sub>2</sub>O (1.5, 3.0, and 4.5 in. H<sub>2</sub>O).] Alternatively, for the vertical portion of the scale, use three evenly spaced reference pressures, one of which is equal to or higher than the highest differential pressure expected in field applications.

10.3.3.2 Acceptance criteria. At each pressure setting, the two pressure readings made using the reference device and the pressure-measuring device being calibrated shall agree to within  $\pm 2$  percent of full scale of the device being calibrated or 0.5 mm H<sub>2</sub>O (0.02 in. H<sub>2</sub>O), whichever is less restrictive. For an inclined-vertical manometer, these requirements shall be met separately using the respective full-scale upper limits of the inclined and vertical portions of the scale. Differential pressure-measuring devices not meeting the  $\pm 2$  percent of full scale or 0.5 mm H<sub>2</sub>O (0.02 in. H<sub>2</sub>O) calibration requirement shall not be used.

10.3.3.3 Exceptions. Any precision manometer that meets the specifications for a reference device in section 6.4.3 and that is not used for field testing does not require calibration, but must be leveled and zeroed before each wind tunnel use. Any pressure device used exclusively for yaw nulling does not require calibration, but shall be checked for responsiveness to rotation of the probe prior to each wind tunnel use.

10.3.4 Calibrate digital inclinometers on each day of wind tunnel or field testing (prior to beginning testing) using the following procedures. Calibrate the inclinometer according to the manufacturer's calibration procedures. In addition, use a triangular block (illustrated in Figure 2F–12) with a known angle, 0, independently determined using a protractor or equivalent device, between two adjacent sides to verify the inclinometer readings.

**Note:** If other angle-measuring devices meeting the provisions of section 6.2.3 are used in place of a digital inclinometer, comparable calibration procedures shall be performed on such devices.) Secure the triangular block in a fixed position. Place the inclinometer on one side of the block (side A) to measure the angle of inclination (R<sub>1</sub>). Repeat this measurement on the adjacent side of the block (side B) using the inclinometer to obtain a second angle reading (R<sub>2</sub>). The difference of the sum of the two readings from  $180^{\circ}$  (i.e.,  $180^{\circ} - R_1 - R_2$ ) shall be within  $\pm 2^{\circ}$  of the known angle,  $\Theta$ 

10.4 Placement of Reference Scribe Line. Prior to the first calibration of a probe, a line shall be permanently inscribed on the main probe sheath to serve as a reference mark for determining yaw angles. Annex C in section 18 of this method gives a guideline for placement of the reference scribe line.

10.4.1 This reference scribe line shall meet the specifications in sections 6.1.6.1 and 6.1.6.3 of this method. To verify that the alignment specification in section 6.1.6.3 is met, secure the probe in a horizontal position and measure the rotational angle of each scribe line and scribe line segment using an angle-measuring device that meets the specifications in section 6.2.1 or 6.2.3. For any scribe line that is longer than 30.5 cm (12 in.), check the line's rotational position at 30.5-cm (12-in.) intervals. For each line segment that is 30.5 cm (12 in.) or less in length, check the rotational position at the two endpoints of the segment. To meet the alignment specification in section 6.1.6.3, the minimum and maximum of all of the rotational angles that are measured along the full length of the main probe must not differ by more than 2°.

**Note:** A short reference scribe line segment [e.g., 15.2 cm (6 in.) or less in length] meeting the alignment specifications in section 6.1.6.3 is fully acceptable under this method. See section 18.1.1.1 of Annex A for an example of a probe marking procedure, suitable for use with a short reference scribe line.

10.4.2 The scribe line should be placed on the probe first and then its offset from the yaw-null position established (as specified in section 10.5). The rotational position of the reference scribe line relative to the yaw-null position of the probe, as determined by the yaw angle calibration procedure in section 10.5, is defined as the reference scribe line rotational offset,  $R_{SLO}$ . The reference scribe line rotational offset shall be recorded and retained as part of the probe's calibration record.

10.4.3 Scribe line for automated probes. A scribe line may not be necessary for an automated probe system if a reference rotational position of the probe is built into the probe system design. For such systems, a "flat" (or comparable, clearly identifiable physical characteristic) should be provided on the probe casing or flange plate to ensure that the reference position of the probe assembly remains in a vertical or horizontal position. The rotational offset of the flat (or comparable, clearly identifiable physical characteristic) needed to orient the reference position of the probe assembly shall be recorded and maintained as part of the automated probe system's specifications.

10.5 Yaw Angle Calibration Procedure. For each probe used to measure yaw angles with this method, a calibration procedure shall be performed in a wind tunnel meeting the specifications in section 10.1 to determine the rotational position of the reference scribe line relative to the probe's yaw-null position. This procedure shall be performed on the main probe with all devices that will be attached to the main probe in the field [such as thermocouples or resistance temperature detectors (RTDs)] that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration. At a minimum, this procedure shall include the following steps.

10.5.1 Align and lock the anglemeasuring device on the reference scribe line. If a marking procedure (such as that described in section 18.1.1.1) is used, align the angle-measuring device on a mark within  $\pm 1^{\circ}$  of the rotational position of the reference scribe line. Lock the angle-measuring device onto the probe sheath at this position.

10.5.2 Zero the pressure-measuring device used for yaw nulling.

10.5.3 Insert the probe assembly into the wind tunnel through the entry port, positioning the probe's impact port at the calibration location. Check the responsiveness of the pressure-measurement device to probe rotation, taking corrective action if the response is unacceptable.

10.5.4 Ensure that the probe is in a horizontal position, using a carpenter's level.

10.5.5 Rotate the probe either clockwise or counterclockwise until a yaw null ( $P_2 = P_3$ ) is obtained.

10.5.6 Use the reading displayed by the angle-measuring device at the yaw-null position to determine the magnitude of the reference scribe line rotational offset, R<sub>SLO</sub>, as defined in section 3.15. Annex D in section 18 of this method provides a recommended procedure for determining the magnitude of  $R_{\rm SLO}$  with a digital inclinometer and a second procedure for determining the magnitude of R<sub>SLO</sub> with a protractor wheel and pointer device. Table 2F-6 presents an example data form and Table 2F-7 is a look-up table with the recommended procedure. Procedures other than those recommended in Annex D in section 18 may be used, if they can determine  $R_{\rm SLO}$  to within  $\pm 1^\circ$  and are explained in detail in the field test report. The algebraic sign of R<sub>SLO</sub> will either be positive, if the rotational position of the reference scribe line (as viewed from the "tail" end of the probe) is clockwise, or negative, if counterclockwise with respect to the probe's yaw-null position. (This is illustrated in Figure 2F-13.)

10.5.7 The steps in sections 10.5.3 through 10.5.6 shall be performed twice at each of the velocities at which the probe will be calibrated (in accordance with section 10.6). Record the values of  $R_{\rm SLO}$ .

10.5.8 The average of all of the  $R_{SLO}$  values shall be documented as the reference scribe line rotational offset for the probe.

10.5.9 Use of reference scribe line offset. The reference scribe line rotational offset shall be used to determine the yaw angle of flow in accordance with section 8.9.4.

10.6 Pitch Angle and Velocity Pressure Calibrations. Use the procedures in sections 10.6.1 through 10.6.16 to generate an appropriate set (or sets) of pitch angle and velocity pressure calibration curves for each probe. The calibration procedure shall be performed on the main probe and all devices that will be attached to the main probe in the field (e.g., thermocouple or RTDs) that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration. (Note: If a sampling nozzle is part of the assembly, a wind tunnel demonstration shall be performed that shows the probe's ability to measure velocity and yaw null is not impaired when the nozzle is drawing a sample.) The calibration procedure involves generating two calibration curves, F1 versus pitch angle and F<sub>2</sub> versus pitch angle. To generate these two curves, F<sub>1</sub> and F<sub>2</sub> shall be derived using Equations 2F-1 and 2F-2, below. Table 2F-8 provides an example wind tunnel calibration data sheet, used to log the measurements needed to derive these two calibration curves.

10.6.1 Calibration velocities. The tester may calibrate the probe at two nominal wind tunnel velocity settings of 18.3 m/sec and 27.4 m/sec (60 ft/sec and 90 ft/sec) and average the results of these calibrations, as described in section 10.6.16.1, in order to generate a set of calibration curves. If this option is selected, this single set of calibration curves may be used for all field applications over the entire velocity range allowed by the method. Alternatively, the tester may customize the probe calibration for a particular field test application (or for a series of applications), based on the expected average velocity(ies) at the test site(s). If this option is selected, generate each set of calibration curves by calibrating the probe at two nominal wind tunnel velocity settings, at least one of which is greater than or equal to the expected average velocity(ies) for the field application(s), and average the results as described in section 10.6.16.1. Whichever calibration option is selected, the probe calibration coefficients (F2 values) obtained at the two nominal calibration velocities shall, for the same pitch angle setting, meet the conditions specified in section 10.6.16.

10.6.2 Pitch angle calibration curve (F-1) versus pitch angle). The pitch angle calibration involves generating a calibration curve of calculated  $F_1$  values versus tested pitch angles, where  $F_1$  is the ratio of the pitch pressure to the velocity pressure, i.e.,

$$F_1 = \frac{(P_4 - P_5)}{(P_1 - P_2)}$$
 Eq. 2F-1

See Figure 2F-14 for an example  $F_1$  versus pitch angle calibration curve.

10.6.3 Velocity calibration curve ( $F_2$  versus pitch angle). The velocity calibration involves generating a calibration curve of the 3–D probe's  $F_2$  coefficient against the tested pitch angles, where

$$F_2 = C_p \sqrt{\frac{\Delta P_{std}}{(P_1 - P_2)}} \qquad Eq. \ 2F-2$$

and

 $\begin{array}{l} C_{p} = calibration \ pitot \ tube \ coefficient, \ and \\ \Delta \ P_{std} = velocity \ pressure \ from \ the \\ calibration \ pitot \ tube. \end{array}$ 

See Figure 2F–15 for an example  $F_2$  versus pitch angle calibration curve.

10.6.4 Connect the tested probe and calibration pitot probe to their respective pressure-measuring devices. Zero the pressure-measuring devices. Inspect and leak-check all pitot lines; repair or replace, if necessary. Turn on the fan, and allow the wind tunnel air flow to stabilize at the first of the two selected nominal velocity settings.

10.6.5 Position the calibration pitot tube at its measurement location (determined as outlined in section 6.11.4.3), and align the tube so that its tip is pointed directly into the flow. Ensure that the entry port surrounding the tube is properly sealed. The calibration pitot tube may either remain in the wind tunnel throughout the calibration, or be removed from the wind tunnel while measurements are taken with the probe being calibrated.

10.6.6 Set up the pitch protractor plate on the tested probe's entry port to establish the pitch angle positions of the probe to within  $\pm 2^{\circ}$ .

10.6.7 Check the zero setting of each pressure-measuring device.

10.6.8 Insert the tested probe into the wind tunnel and align it so that its  $P_1$  pressure port is pointed directly into the flow and is positioned within the calibration location (as defined in section 3.20). Secure the probe at the 0° pitch angle position. Ensure that the entry port surrounding the probe is properly sealed.

10.6.9 Read the differential pressure from the calibration pitot tube ( $\Delta P_{std}$ ), and record its value. Read the barometric pressure to within ±2.5 mm Hg (±0.1 in. Hg) and the temperature in the wind tunnel to within 0.6°C (1°F). Record these values on a data form similar to Table 2F–8.

10.6.10 After the tested probe's differential pressure gauges have had sufficient time to stabilize, yaw null the probe, then obtain differential pressure readings for  $(P_1-P_2)$  and  $(P_4-P_5)$ . Record the yaw angle and differential pressure readings. After taking these readings, ensure that the tested probe has remained at the yaw-null position.

10.6.11 Either take paired differential pressure measurements with both the calibration pitot tube and tested probe (according to sections 10.6.9 and 10.6.10) or take readings only with the tested probe (according to section 10.6.10) in 5° increments over the pitch-angle range for which the probe is to be calibrated. The calibration pitch-angle range shall be symmetric around 0° and shall exceed the largest pitch angle expected in the field by 5°. At a minimum, probes shall be calibrated over the range of  $-15^{\circ}$  to  $+15^{\circ}$ . If paired calibration pitot tube and tested probe measurements are not taken at each pitch angle setting, the differential pressure from the calibration pitot tube shall be read, at a minimum, before taking the tested probe's differential pressure reading at the first pitch angle setting and after taking the tested probe's differential pressure readings at the last pitch angle setting in each replicate.

10.6.12 Perform a second replicate of the procedures in sections 10.6.5 through 10.6.11 at the same nominal velocity setting.

10.6.13 For each replicate, calculate the  $F_1$  and  $F_2$  values at each pitch angle. At each pitch angle, calculate the percent difference between the two  $F_2$  values using Equation 2F-3.

$$\text{\%Diff} = \frac{F_2^{\text{max}} - F_2^{\text{min}}}{F_2^{\text{min}}} \times 100\% \text{ Eq. 2F-3}$$

#### Eq. 2F-3

If the percent difference is less than or equal to 2 percent, calculate an average F<sub>1</sub> value and an average F<sub>2</sub> value at that pitch angle. If the percent difference is greater than 2 percent and less than or equal to 5 percent, perform a third repetition at that angle and calculate an average F1 value and an average  $F_2$  value using all three repetitions. If the percent difference is greater than 5 percent, perform four additional repetitions at that angle and calculate an average F<sub>1</sub> value and an average F<sub>2</sub> value using all six repetitions. When additional repetitions are required at any pitch angle, move the probe by at least 5° and then return to the specified pitch angle before taking the next measurement. Record the average values on a form similar to Table 2F-9.

10.6.14 Repeat the calibration procedures in sections 10.6.5 through 10.6.13 at the second selected nominal wind tunnel velocity setting.

10.6.15 Velocity drift check. The following check shall be performed, except when paired calibration pitot tube and tested probe pressure measurements are taken at each pitch angle setting. At each velocity setting, calculate the percent difference between consecutive differential pressure measurements made with the calibration pitot tube. If a measurement differs from the previous measurement by more than 2 percent or 0.25 mm H<sub>2</sub>O (0.01 in. H<sub>2</sub>O), whichever is less restrictive, the calibration data collected between these calibration pitot tube measurements may not be used, and the measurements shall be repeated.

10.6.16 Compare the averaged  $F_2$  coefficients obtained from the calibrations at the two selected nominal velocities, as follows. At each pitch angle setting, use Equation 2F–3 to calculate the difference between the corresponding average  $F_2$  values at the two calibration velocities. At each pitch angle in the  $-15^{\circ}$  to  $+15^{\circ}$  range, the percent difference between the average  $F_2$  values shall not exceed 3.0 percent. For pitch angles outside this range (i.e., less than  $-15^{\circ}0$  and greater than  $+15^{\circ}$ ), the percent difference shall not exceed 5.0 percent.

10.6.16.1 If the applicable specification in section 10.6.16 is met at each pitch angle setting, average the results obtained at the two nominal calibration velocities to produce a calibration record of  $F_1$  and  $F_2$  at each pitch angle tested. Record these values on a form similar to Table 2F–9. From these values, generate one calibration curve representing  $F_1$  versus pitch angle and a second curve representing  $F_2$  versus pitch angle. Computer spreadsheet programs may be used to graph the calibration data and to develop polynomial equations that can be used to calculate pitch angles and axial velocities.

10.6.16.2 If the applicable specification in section 10.6.16 is exceeded at any pitch angle setting, the probe shall not be used unless: (1) the calibration is repeated at that pitch angle and acceptable results are obtained or (2) values of  $F_1$  and  $F_2$  are obtained at two nominal velocities for which the specifications in section 10.6.16 are met across the entire pitch angle range.

10.7 Recalibration. Recalibrate the probe using the procedures in section 10 either within 12 months of its first field use after its most recent calibration or after 10 field tests (as defined in section 3.4), whichever occurs later. In addition, whenever there is visible damage to the 3-D head, the probe shall be recalibrated before it is used again.

10.8 Calibration of pressure-measuring devices used in field tests. Before its initial use in a field test, calibrate each pressuremeasuring device (except those used exclusively for yaw nulling) using the threepoint calibration procedure described in section 10.3.3. The device shall be recalibrated according to the procedure in section 10.3.3 no later than 90 days after its first field use following its most recent calibration. At the discretion of the tester, more frequent calibrations (e.g., after a field test) may be performed. No adjustments, other than adjustments to the zero setting, shall be made to the device between calibrations.

10.8.1 Post-test calibration check. A single-point calibration check shall be performed on each pressure-measuring device after completion of each field test. At the discretion of the tester, more frequent single-point calibration checks (e.g., after one or more field test runs) may be performed. It is recommended that the post-test check be performed before leaving the field test site. The check shall be performed at a pressure between 50 and 90 percent of full scale by taking a common pressure reading with the tested device and a reference pressuremeasuring device (as described in section 6.4.4) or by challenging the tested device with a reference pressure source (as described in section 6.4.4) or by performing an equivalent check using a reference device approved by the Administrator.

10.8.2 Acceptance criterion. At the selected pressure setting, the pressure readings made using the reference device and the tested device shall agree to within 3 percent of full scale of the tested device or 0.8 mm H<sub>2</sub>O (0.03 in. H<sub>2</sub>O), whichever is less restrictive. If this specification is met, the test data collected during the field test are valid. If the specification is not met, all test data collected since the last successful calibration or calibration check are invalid and shall be repeated using a pressure-measuring device with a current, valid calibration. Any device that fails the calibration check shall not be used in a field test until a successful recalibration is performed according to the procedures in section 10.3.3.

10.9 Temperature Gauges. Same as Method 2, section 4.3. The alternative thermocouple calibration procedures outlined in Emission Measurement Center (EMC) Approved Alternative Method (ALT-011) "Alternative Method 2 Thermocouple Calibration Procedure" may be performed. Temperature gauges shall be calibrated no more than 30 days prior to the start of a field test or series of field tests and recalibrated no more than 30 days after completion of a field test or series of field tests.

10.10 Barometer. Same as Method 2, section 4.4. The barometer shall be calibrated no more than 30 days prior to the start of a field test or series of field tests.

#### 11.0 Analytical Procedure

Sample collection and analysis are concurrent for this method (see section 8.0).

#### 12.0 Data Analysis and Calculations

These calculations use the measured yaw angle, derived pitch angle, and the differential pressure and temperature measurements at individual traverse points to derive the axial flue gas velocity ( $v_{a(i)}$ ) at each of those points. The axial velocity values at all traverse points that comprise a full stack or duct traverse are then averaged to obtain the average axial flue gas velocity ( $v_a$  (avg)). Round off figures only in the final calculation of reported values.

12.1 Nomenclature

- A = Cross-sectional area of stack or duct,  $m^2$  (ft<sup>2</sup>).
- $B_{ws} =$  Water vapor in the gas stream (from Method 4 or alternative), proportion by volume.
- Kp = Conversion factor (a constant),

$$34.97 \frac{\mathrm{m}}{\mathrm{sec}} \left[ \frac{(\mathrm{g/g} \cdot \mathrm{mole})(\mathrm{mm} \mathrm{Hg})}{(^{\circ} \mathrm{K})(\mathrm{mm} \mathrm{H}_{2} \mathrm{O})} \right]^{1/2}$$

for the metric system, and

$$85.49 \frac{\text{ft}}{\text{sec}} \left[ \frac{(\text{lb/lb-mole})(\text{in. Hg})}{(^{\circ}\text{R})(\text{in. H}_2\text{O})} \right]^{1/2}$$

for the English system.

- $\label{eq:Md} \begin{array}{l} M_d = Molecular \ weight \ of \ stack \ or \ duct \ gas, \\ dry \ basis \ (see \ section \ 8.13), \ g/g-mole \ (lb/ \ lb-mole). \end{array}$
- M<sub>s</sub> = Molecular weight of stack or duct gas, wet basis, g/g-mole (lb/lb-mole).

 $M_s = M_d(1 - B_{ws}) + 18.0B_{ws}$  Eq. 2F-4

- P<sub>bar</sub> = Barometric pressure at measurement site, mm Hg (in. Hg).
- $P_g$  = Stack or duct static pressure, mm H<sub>2</sub>O (in. H<sub>2</sub>O).
- $P_s$  = Absolute stack or duct pressure, mm Hg (in. Hg),

$$P_{s} = P_{bar} + \frac{P_{g}}{13.6}$$
 Eq. 2F-5

- $P_{std}$  = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).
- 13.6 = Conversion from mm  $H_2O$  (in.  $H_2O$ ) to mm Hg (in. Hg).
- $\label{eq:Qsd} \begin{aligned} Q_{sd} = Average \ dry-basis \ volumetric \ stack \ or \\ duct \ gas \ flow \ rate \ corrected \ to \ standard \\ conditions, \ dscm/hr \ (dscf/hr). \end{aligned}$
- Q<sub>sw</sub> = Average wet-basis volumetric stack or duct gas flow rate corrected to standard conditions, wscm/hr (wscf/hr).

 $T_{s(avg)}$  = Average absolute stack or duct gas

temperature across all traverse points.  $t_{s(i)} =$  Stack or duct gas temperature, C (F), at traverse point i.

 $T_{s(i)}$  = Absolute stack or duct gas temperature, K (R), at traverse point i,

$$T_{s(i)} = 273 + t_{s(i)}$$
 Eq. 2F-6

for the metric system, and

$$T_{s(i)} = 460 + t_{s(i)}$$
 Eq. 2F-7

for the English system.

- $T_{std}$  = Standard absolute temperature, 293°K (528°R).
- $F_{1(i)}$  = Pitch angle ratio, applicable at traverse point i, dimensionless.
- $F_{2(i)} = \text{3-D probe velocity calibration} \\ \text{coefficient, applicable at traverse point i,} \\ \text{dimensionless.}$
- $(P_4-P_5)_i$  = Pitch differential pressure of stack or duct gas flow, mm H<sub>2</sub>O (in. H<sub>2</sub>O), at traverse point i.
- $(P_1-P_2)_i = Velocity head (differential pressure)$ of stack or duct gas flow, mm H<sub>2</sub>O (in. H<sub>2</sub>O), at traverse point i.
- v<sub>a(i)</sub> = Reported stack or duct gas axial velocity, m/sec (ft/sec), at traverse point i.
- $v_{a(avg)}$  = Average stack or duct gas axial velocity, m/sec (ft/sec), across all traverse points.

3,600 = Conversion factor, sec/hr.

18.0 = Molecular weight of water, g/g-mole (lb/lb-mole).

 $\theta_{y(i)} = Yaw \text{ angle, degrees, at traverse point} \\ i.$ 

 $\theta_{p(i)}$  = Pitch angle, degrees, at traverse point i.

n = Number of traverse points.

12.2 Traverse Point Velocity Calculations. Perform the following calculations from the measurements obtained at each traverse point.

12.2.1 Selection of calibration curves. Select calibration curves as described in section 10.6.1.

12.2.2 Traverse point pitch angle ratio. Use Equation 2F–1, as described in section 10.6.2, to calculate the pitch angle ratio,  $F_{1(i)}$ , at each traverse point.

12.2.3 Pitch angle. Use the pitch angle ratio,  $F_{1(i)}$ , to derive the pitch angle,  $\theta_{p(i)}$ , at traverse point i from the  $F_1$  versus pitch angle calibration curve generated under section 10.6.16.1.

12.2.4 Velocity calibration coefficient. Use the pitch angle,  $\theta_{p(i)}$ , to obtain the probe velocity calibration coefficient,  $F_{2(i)}$ , at traverse point i from the "velocity pressure calibration curve," i.e., the  $F_2$  versus pitch angle calibration curve generated under section 10.6.16.1.

12.2.5 Axial velocity. Use the following equation to calculate the axial velocity,  $v_{a(i)}$ , from the differential pressure  $(P_1-P_2)_i$  and yaw angle,  $\theta_{y(i)}$ , measured at traverse point i and the previously calculated values for the velocity calibration coefficient,  $F_{2(i)}$ , absolute stack or duct standard temperature,  $T_{s(i)}$ , absolute stack or duct pressure,  $P_s$ , molecular weight,  $M_s$ , and pitch angle, " $\theta_{p(i)}$ .

$$v_{a(i)} = K_{p}F_{2(i)}\sqrt{\frac{(P_{1} - P_{2})_{i}T_{s(i)}}{P_{s}M_{s}}}(\cos\theta_{y(i)})(\cos\theta_{p(i)})$$
 Eq. 2F-8

12.2.6 Handling multiple measurements at a traverse point. For pressure or temperature devices that take multiple measurements at a traverse point, the multiple measurements (or where applicable, their square roots) may first be averaged and the resulting average values used in the equations above. Alternatively, the individual measurements may be used in the equations above and the resulting multiple calculated values may then be averaged to obtain a single traverse point value. With either approach, all of the individual measurements recorded at a traverse point must be used in calculating the applicable traverse point value.

12.3 Average Axial Velocity in Stack or Duct. Use the reported traverse point axial velocity in the following equation.

$$v_{a(avg)} = \frac{\sum_{i=1}^{n} v_{a(i)}}{n}$$
 Eq. 2F-9

12.4 Acceptability of Results. The test results are acceptable and the calculated value of  $v_{a(avg)}$  may be reported as the average axial velocity for the test run if the conditions in either section 12.4.1 or 12.4.2 are met.

12.4.1 The calibration curves were generated at nominal velocities of 18.3 m/sec and 27.4 m/sec (60 ft/sec and 90 ft/sec).

12.4.2 The calibration curves were generated at nominal velocities other than 18.3 m/sec and 27.4 m/sec (60 ft/sec and 90 ft/sec), and the value of  $v_{a(avg)}$  obtained using Equation 2F–9 is less than or equal to at least

$$Q_{sw} = 3,600 \left( v_{a(avg)} \right) (A) \left( \frac{T_{std}}{T_{s(avg)}} \right) \left( \frac{P_s}{P_{std}} \right) \qquad \text{Eq. 2F-10}$$

12.6 Average Gas Dry Volumetric Flow Rate in Stack or Duct. Use the following equation to compute the average volumetric flow rate on a dry basis.

$$Q_{sd} = 3,600(1 - B_{ws})(v_{a(avg)})(A)\left(\frac{T_{std}}{T_{s(avg)}}\right)\left(\frac{P_s}{P_{std}}\right) \qquad \text{Eq. 2F-11}$$

- 14.0 Pollution Prevention. [Reserved]
- 15.0 Waste Management. [Reserved]
- 16.0 Reporting

16.1 Field Test Reports. Field test reports shall be submitted to the Agency according to applicable regulatory requirements. Field test reports should, at a minimum, include the following elements.

16.1.1 Description of the source. This should include the name and location of the test site, descriptions of the process tested, a description of the combustion source, an accurate diagram of stack or duct crosssectional area at the test site showing the dimensions of the stack or duct, the location of the test ports, and traverse point locations and identification numbers or codes. It should also include a description and diagram of the stack or duct layout, showing the distance of the test location from the nearest upstream and downstream disturbances and all structural elements (including breachings, baffles, fans, straighteners, etc.) affecting the flow pattern. If the source and test location descriptions have been previously submitted to the Agency in a document (e.g., a monitoring plan or test plan), referencing the document in lieu of including this information in the field test report is acceptable.

16.1.2 Field test procedures. These should include a description of test equipment and test procedures. Testing conventions, such as traverse point numbering and measurement sequence (e.g., sampling from center to wall, or wall to center), should be clearly stated. Test port identification and directional reference for each test port should be included on the appropriate field test data sheets.

16.1.3 Field test data.

16.1.3.1 Summary of results. This summary should include the dates and times of testing and the average axial gas velocity and the average flue gas volumetric flow results for each run and tested condition.

16.1.3.2 Test data. The following values for each traverse point should be recorded and reported:

- (a)  $P_1$ - $P_2$  and  $P_4$ - $P_5$  differential pressures
- (b) Stack or duct gas temperature at traverse point i  $(t_{s(i)})$
- (c) Absolute stack or duct gas temperature at traverse point i  $(T_{s(i)})$
- (d) Yaw angle at each traverse point i  $(\theta_{y(i)})$

(e) Pitch angle at each traverse point i  $(\theta_{p(i)})$ 

(f) Stack or duct gas axial velocity at traverse

point i (v<sub>a(i)</sub>) 16.1.3.3 The following values should be

- reported once per run: (a) Water vapor in the gas stream (from
- Method 4 or alternative), proportion by volume ( $B_{ws}$ ), measured at the frequency specified in the applicable regulation

one of the nominal velocities used to derive the  $F_1 \mbox{ and } F_2$  calibration curves.

12.4.3 If the conditions in neither section 12.4.1 nor section 12.4.2 are met, the test results obtained in Equation 2F-9 are not acceptable, and the steps in sections 12.2 and 12.3 must be repeated using a set of  $F_1$  and  $F_2$  calibration curves that satisfies the conditions specified in section 12.4.1 or 12.4.2.

12.5 Average Gas Wet Volumetric Flow Rate in Stack or Duct. Use the following equation to compute the average volumetric flow rate on a wet basis.

- (b) Molecular weight of stack or duct gas, dry basis (M<sub>d</sub>)
- (c) Molecular weight of stack or duct gas, wet basis (M<sub>s</sub>)
- (d) Stack or duct static pressure  $(P_g)$
- (e) Absolute stack or duct pressure  $(P_s)$
- (f) Carbon dioxide concentration in the flue gas, dry basis ( $\%_d$  CO<sub>2</sub>)
- (g) Oxygen concentration in the flue gas, dry basis ( $\%_d O_2$ )
- (h) Average axial stack or duct gas velocity  $(v_{a(avg)})$  across all traverse points
- (i) Gas volumetric flow rate corrected to standard conditions, dry or wet basis as required by the applicable regulation ( $Q_{sd}$  or  $Q_{sw}$ )
- 16.1.3.4 The following should be reported once per complete set of test runs:
- (a) Cross-sectional area of stack or duct at the test location (A)
- (b) Measurement system response time (sec)(c) Barometric pressure at measurement site (P<sub>bar</sub>)

16.1.4 Calibration data. The field test report should include calibration data for all probes and test equipment used in the field test. At a minimum, the probe calibration data reported to the Agency should include the following:

- (a) Date of calibration
- (b) Probe type
- (c) Probe identification number(s) or code(s)
- (d) Probe inspection sheets

- (e) Pressure measurements and intermediate calculations of  $F_1$  and  $F_2$  at each pitch angle used to obtain calibration curves in accordance with section 10.6 of this method
- (f) Calibration curves (in graphic or equation format) obtained in accordance with sections 10.6.11 of this method
- (g) Description and diagram of wind tunnel used for the calibration, including dimensions of cross-sectional area and position and size of the test section
- (h) Documentation of wind tunnel qualification tests performed in accordance with section 10.1 of this method

16.1.5 Quality Assurance. Specific quality assurance and quality control procedures used during the test should be described.

- 18.0 Annexes

Annex A, C, and D describe recommended procedures for meeting certain provisions in sections 8.3, 10.4, and 10.5 of this method. Annex B describes procedures to be followed when using the protractor wheel and pointer assembly to measure yaw angles, as provided under section 8.9.1.

18.1 Annex A—Rotational Position Check. The following are recommended procedures that may be used to satisfy the rotational position check requirements of section 8.3 of this method and to determine the anglemeasuring device rotational offset (RADO).

18.1.1 Rotational position check with probe outside stack. Where physical constraints at the sampling location allow full assembly of the probe outside the stack and insertion into the test port, the following procedures should be performed before the start of testing. Two angle-measuring devices that meet the specifications in section 6.2.1 or 6.2.3 are required for the rotational position check. An angle measuring device whose position can be independently adjusted (e.g., by means of a set screw) after being locked into position on the probe sheath shall not be used for this check unless the independent adjustment is set so that the device performs exactly like a device without the capability for independent adjustment That is, when aligned on the probe such a device must give the same reading as a device that does not have the capability of being independently adjusted. With the fully assembled probe (including probe shaft extensions, if any) secured in a horizontal position, affix one yaw angle-measuring device to the probe sheath and lock it into position on the reference scribe line specified in section 6.1.6.1. Position the second anglemeasuring device using the procedure in section 18.1.1.1 or 18.1.1.2.

18.1.1.1 Marking procedure. The procedures in this section should be performed at each location on the fully assembled probe where the yaw anglemeasuring device will be mounted during the velocity traverse. Place the second yaw anglemeasuring device on the main probe sheath (or extension) at the position where a vaw angle will be measured during the velocity traverse. Adjust the position of the second angle-measuring device until it indicates the same angle  $(\pm 1^{\circ})$  as the reference device, and affix the second device to the probe sheath (or extension). Record the angles indicated by the two angle-measuring devices on a form similar to Table 2F-2. In this position, the second angle-measuring device is considered to be properly positioned for yaw angle measurement. Make a mark, no wider than 1.6 mm (1/16 in.), on the probe sheath (or extension), such that the yaw anglemeasuring device can be re-affixed at this same properly aligned position during the velocity traverse.

18.1.1.2 Procedure for probe extensions with scribe lines. If, during a velocity traverse the angle-measuring device will be affixed to a probe extension having a scribe line as specified in section 6.1.6.2, the following procedure may be used to align the extension's scribe line with the reference scribe line instead of marking the extension as described in section 18.1.1.1. Attach the probe extension to the main probe. Align and lock the second angle-measuring device on the probe extension's scribe line. Then, rotate the extension until both measuring devices

indicate the same angle  $(\pm 1^{\circ})$ . Lock the extension at this rotational position. Record the angles indicated by the two anglemeasuring devices on a form similar to Table 2F–2. An angle-measuring device may be aligned at any position on this scribe line during the velocity traverse, if the scribe line meets the alignment specification in section 6.1.6.3.

18.1.1.3 Post-test rotational position check. If the fully assembled probe includes one or more extensions, the following check should be performed immediately after the completion of a velocity traverse. At the discretion of the tester, additional checks may be conducted after completion of testing at any sample port. Without altering the alignment of any of the components of the probe assembly used in the velocity traverse, secure the fully assembled probe in a horizontal position. Affix an angle-measuring device at the reference scribe line specified in section 6.1.6.1. Use the other anglemeasuring device to check the angle at each location where the device was checked prior to testing. Record the readings from the two angle-measuring devices.

18.1.2 Rotational position check with probe in stack. This section applies only to probes that, due to physical constraints, cannot be inserted into the test port as fully assembled with all necessary extensions needed to reach the inner-most traverse point(s).

18.1.2.1 Perform the out-of-stack procedure in section 18.1.1 on the main probe and any attached extensions that will be initially inserted into the test port.

18.1.2.2 Use the following procedures to perform additional rotational position check(s) with the probe in the stack, each time a probe extension is added. Two anglemeasuring devices are required. The first of these is the device that was used to measure yaw angles at the preceding traverse point, left in its properly aligned measurement position. The second angle-measuring device is positioned on the added probe extension. Use the applicable procedures in section 18.1.1.1 or 18.1.1.2 to align, adjust, lock, and mark (if necessary) the position of the second angle-measuring device to within ±1° of the first device. Record the readings of the two devices on a form similar to Table 2F-2

18.1.2.3 The procedure in section 18.1.2.2 should be performed at the first port where measurements are taken. The procedure should be repeated each time a probe extension is re-attached at a subsequent port, unless the probe extensions are designed to be locked into a mechanically fixed rotational position (e.g., through use of interlocking grooves), which can be reproduced from port to port as specified in section 8.3.5.2.

18.2 Annex B—Angle Measurement Protocol for Protractor Wheel and Pointer Device. The following procedure shall be used when a protractor wheel and pointer assembly, such as the one described in section 6.2.2 and illustrated in Figure 2F–7 is used to measure the yaw angle of flow. With each move to a new traverse point, unlock, re-align, and re-lock the probe, anglepointer collar, and protractor wheel to each other. At each such move, particular attention is required to ensure that the scribe line on the angle pointer collar is either aligned with the reference scribe line on the main probe sheath or is at the rotational offset position established under section 8.3.1. The procedure consists of the following steps:

18.2.1 Affix a protractor wheel to the entry port for the test probe in the stack or duct.

18.2.2 Orient the protractor wheel so that the 0° mark corresponds to the longitudinal axis of the stack or duct. For stacks, vertical ducts, or ports on the side of horizontal ducts, use a digital inclinometer meeting the specifications in section 6.2.1 to locate the 0° orientation. For ports on the top or bottom of horizontal ducts, identify the longitudinal axis at each test port and permanently mark the duct to indicate the 0° orientation. Once the protractor wheel is properly aligned, lock it into position on the test port.

18.2.3 Move the pointer assembly along the probe sheath to the position needed to take measurements at the first traverse point. Align the scribe line on the pointer collar with the reference scribe line or at the rotational offset position established under section 8.3.1. Maintaining this rotational alignment, lock the pointer device onto the probe sheath. Insert the probe into the entry port to the depth needed to take measurements at the first traverse point.

18.2.4 Perform the yaw angle determination as specified in sections 8.9.3 and 8.9.4 and record the angle as shown by the pointer on the protractor wheel. Then, take velocity pressure and temperature measurements in accordance with the procedure in section 8.9.5. Perform the alignment check described in section 8.9.6.

18.2.5 After taking velocity pressure measurements at that traverse point, unlock the probe from the collar and slide the probe through the collar to the depth needed to reach the next traverse point.

18.2.6 Align the scribe line on the pointer collar with the reference scribe line on the main probe or at the rotational offset position established under section 8.3.1. Lock the collar onto the probe.

18.2.7 Repeat the steps in sections 18.2.4 through 18.2.6 at the remaining traverse points accessed from the current stack or duct entry port.

18.2.8 After completing the measurement at the last traverse point accessed from a port, verify that the orientation of the protractor wheel on the test port has not changed over the course of the traverse at that port. For stacks, vertical ducts, or ports on the side of horizontal ducts, use a digital inclinometer meeting the specifications in section 6.2.1 to check the rotational position of the 0° mark on the protractor wheel. For ports on the top or bottom of horizontal ducts, observe the alignment of the angle wheel 0° mark relative to the permanent 0° mark on the duct at that test port. If these observed comparisons exceed  $\pm 2^{\circ}$  of  $0^{\circ}$ , all angle and pressure measurements taken at that port since the protractor wheel was last locked into position on the port shall be repeated.

18.2.9 Move to the next stack or duct entry port and repeat the steps in sections 18.2.1 through 18.2.8.

18.3 Annex C—Guideline for Reference Scribe Line Placement. Use of the following guideline is recommended to satisfy the requirements of section 10.4 of this method. The rotational position of the reference scribe line should be either 90° or 180° from the probe's impact pressure port.

18.4 Annex D—Determination of Reference Scribe Line Rotational Offset. The following procedures are recommended for determining the magnitude and sign of a probe's reference scribe line rotational offset, R<sub>SLO</sub>. Separate procedures are provided for two types of angle-measuring devices: digital inclinometers and protractor wheel and pointer assemblies.

18.4.1 Perform the following procedures on the main probe with all devices that will be attached to the main probe in the field [such as thermocouples or resistance temperature detectors (RTDs)] that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration.

18.4.2 The procedures below assume that the wind tunnel duct used for probe calibration is horizontal and that the flow in the calibration wind tunnel is axial as determined by the axial flow verification check described in section 10.1.2. Anglemeasuring devices are assumed to display angles in alternating 0° to 90° and 90° to 0° intervals. If angle-measuring devices with other readout conventions are used or if other calibration wind tunnel duct configurations are used, make the appropriate calculational corrections.

18.4.2.1 Position the angle-measuring device in accordance with one of the following procedures.

18.4.2.1.1 If using a digital inclinometer, affix the calibrated digital inclinometer to the probe. If the digital inclinometer can be independently adjusted after being locked into position on the probe sheath (e.g., by means of a set screw), the independent adjustment must be set so that the device performs exactly like a device without the capability for independent adjustment. That is, when aligned on the probe the device must give the same readings as a device that does not have the capability of being independently adjusted. Either align it directly on the reference scribe line or on a mark aligned with the scribe line determined according to the procedures in section 18.1.1.1. Maintaining this rotational alignment, lock the digital inclinometer onto the probe sheath.

18.4.2.1.2 If using a protractor wheel and pointer device, orient the protractor wheel on the test port so that the  $0^{\circ}$  mark is aligned with the longitudinal axis of the wind tunnel duct. Maintaining this alignment, lock the wheel into place on the wind tunnel test port. Align the scribe line on the pointer collar with the reference scribe line or with a mark aligned with the reference scribe line, as determined under section 18.1.1.1. Maintaining this rotational alignment, lock the pointer device onto the probe sheath.

18.4.2.2 Zero the pressure-measuring device used for yaw nulling.

18.4.2.3 Insert the probe assembly into the wind tunnel through the entry port,

positioning the probe's impact port at the calibration location. Check the responsiveness of the pressure-measuring device to probe rotation, taking corrective action if the response is unacceptable.

18.4.2.4 Ensure that the probe is in a horizontal position using a carpenter's level.

18.4.2.5 Rotate the probe either clockwise or counterclockwise until a yaw null  $(P_2=P_3)$  is obtained.

18.4.2.6 Read and record the value of  $T_{null}$ , the angle indicated by the anglemeasuring device at the yaw-null position. Record the angle reading on a form similar to Table 2F–6. Do not associate an algebraic sign with this reading.

18.4.2.7 Determine the magnitude and algebraic sign of the reference scribe line rotational offset,  $R_{SLO}$ . The magnitude of  $R_{SLO}$  will be equal to either  $T_{null}$  or (90° –  $T_{null}$ ), depending on the angle-measuring device used. (See Table 2F–7 for a summary.) The algebraic sign of  $R_{SLO}$  will either be positive, if the rotational position of the reference scribe line is clockwise, or negative, if counterclockwise with respect to the probe's

yaw-null position. Figure 2F–13 illustrates how the magnitude and sign of  $R_{\rm SLO}$  are determined.

18.4.2.8 Perform the steps in sections 18.4.2.3 through 18.4.2.7 twice at each of the two calibration velocities selected for the probe under section 10.6. Record the values of  $R_{\rm SLO}$  in a form similar to Table 2F–6.

18.4.2.9 The average of all  $R_{\rm SLO}$  values is the reference scribe line rotational offset for the probe.

## Method 2G—Determination of Stack Gas Velocity and Volumetric Flow Rate With Two-Dimensional Probes

**Note:** This method does not include all of the specifications (e.g., equipment and supplies) and procedures (e.g., sampling) essential to its performance. Some material has been incorporated from other methods in this part. Therefore, to obtain reliable results, those using this method should have a thorough knowledge of at least the following additional test methods: Methods 1, 2, 3 or 3A, and 4.

## 1.0 Scope and Application

1.1 This method is applicable for the determination of yaw angle, near-axial velocity, and the volumetric flow rate of a gas stream in a stack or duct using a two-dimensional (2–D) probe.

### 2.0 Summary of Method

2.1 A 2–D probe is used to measure the velocity pressure and the yaw angle of the flow velocity vector in a stack or duct. Alternatively, these measurements may be made by operating one of the three-dimensional (3–D) probes described in Method 2F, in yaw determination mode only. From these measurements and a determination of the stack gas density, the average near-axial velocity of the stack gas is calculated. The near-axial velocity accounts for the yaw, but not the pitch, component of flow. The average gas volumetric flow rate in the stack or duct is then determined from the average near-axial velocity.

### 3.0 Definitions

3.1. Angle-measuring Device Rotational Offset ( $R_{ADO}$ ). The rotational position of an angle-measuring device relative to the reference scribe line, as determined during the pre-test rotational position check described in section 8.3.

3.2 *Calibration Pitot Tube.* The standard (Prandtl type) pitot tube used as a reference when calibrating a probe under this method.

3.3 *Field Test.* À set of measurements conducted at a specific unit or exhaust stack/ duct to satisfy the applicable regulation (e.g., a three-run boiler performance test, a singleor multiple-load nine-run relative accuracy test).

3.4 Full Scale of Pressure-measuring Device. Full scale refers to the upper limit of the measurement range displayed by the device. For bi-directional pressure gauges, full scale includes the entire pressure range from the lowest negative value to the highest positive value on the pressure scale.

3.5 *Main probe.* Refers to the probe head and that section of probe sheath directly attached to the probe head. The main probe sheath is distinguished from probe extensions, which are sections of sheath added onto the main probe to extend its reach.

3.6 *"May," "Must," "Shall," "Should,"* and the imperative form of verbs.

3.6.1 " $\hat{May}$ " is used to indicate that a provision of this method is optional.

3.6.2 *"Must," "Shall,"* and the imperative form of verbs (such as "record" or "enter") are used to indicate that a provision of this method is mandatory.

3.6.3 *"Should"* is used to indicate that a provision of this method is not mandatory, but is highly recommended as good practice.

3.7 *Method 1.* Refers to 40 CFR part 60, appendix A, "Method 1—Sample and velocity traverses for stationary sources."

3.8 *Method 2.* Refers to 40 CFR part 60, appendix A, "Method 2—Determination of stack gas velocity and volumetric flow rate (Type S pitot tube)."

3.9 *Method 2F.* Refers to 40 CFR part 60, appendix A, "Method 2F—Determination of stack gas velocity and volumetric flow rate with three-dimensional probes."

3.10 Near-axial Velocity. The velocity vector parallel to the axis of the stack or duct that accounts for the yaw angle component of gas flow. The term "near-axial" is used herein to indicate that the velocity and volumetric flow rate results account for the measured yaw angle component of flow at each measurement point.

3.11 Nominal Velocity. Refers to a wind tunnel velocity setting that approximates the actual wind tunnel velocity to within  $\pm 1.5$  m/ sec ( $\pm 5$  ft/sec).

3.12 Pitch Angle. The angle between the axis of the stack or duct and the pitch component of flow, i.e., the component of the total velocity vector in a plane defined by the traverse line and the axis of the stack or duct. (Figure 2G-1 illustrates the "pitch plane.") From the standpoint of a tester facing a test port in a vertical stack, the pitch component of flow is the vector of flow moving from the center of the stack toward or away from that test port. The pitch angle is the angle described by this pitch component of flow and the vertical axis of the stack.

3.13 *Readability.* For the purposes of this method, readability for an analog measurement device is one half of the smallest scale division. For a digital measurement device, it is the number of decimals displayed by the device.

3.14 *Reference Scribe Line*. A line permanently inscribed on the main probe sheath (in accordance with section 6.1.5.1) to serve as a reference mark for determining yaw angles.

3.15 Reference Scribe Line Rotational Offset ( $R_{SLO}$ ). The rotational position of a probe's reference scribe line relative to the probe's yaw-null position, as determined during the yaw angle calibration described in section 10.5.

3.16 *Response Time.* The time required for the measurement system to fully respond to a change from zero differential pressure and ambient temperature to the stable stack or duct pressure and temperature readings at a traverse point.

3.17 *Tested Probe.* A probe that is being calibrated.

3.18 *Three-dimensional (3–D) Probe.* A directional probe used to determine the velocity pressure and the yaw and pitch angles in a flowing gas stream.

3.19 *Two-dimensional (2–D) Probe.* A directional probe used to measure velocity pressure and yaw angle in a flowing gas stream.

3.20 *Traverse Line.* A diameter or axis extending across a stack or duct on which measurements of velocity pressure and flow angles are made.

Wind Tunnel Calibration Location. 3.21 A point, line, area, or volume within the wind tunnel test section at, along, or within which probes are calibrated. At a particular wind tunnel velocity setting, the average velocity pressures at specified points at, along, or within the calibration location shall vary by no more than 2 percent or 0.3 mm H<sub>2</sub>0 (0.01 in. H<sub>2</sub>O), whichever is less restrictive, from the average velocity pressure at the calibration pitot tube location. Air flow at this location shall be axial, i.e., yaw and pitch angles within ±3 of 0. Compliance with these flow criteria shall be demonstrated by performing the procedures prescribed in sections 10.1.1 and 10.1.2. For circular tunnels, no part of the calibration location may be closer to the tunnel wall than 10.2 cm (4 in.) or 25 percent of the tunnel diameter, whichever is farther from the wall. For elliptical or rectangular tunnels, no part of the calibration location may be closer to the tunnel wall than 10.2 cm (4 in.) or 25 percent of the applicable cross-sectional axis, whichever is farther from the wall.

3.22 Wind Tunnel with Documented Axial Flow. A wind tunnel facility documented as meeting the provisions of sections 10.1.1 (velocity pressure crosscheck) and 10.1.2 (axial flow verification) using the procedures described in these sections or alternative procedures determined to be technically equivalent.

3.23 Yaw Angle. The angle between the axis of the stack or duct and the yaw component of flow, i.e., the component of the total velocity vector in a plane perpendicular to the traverse line at a particular traverse point. (Figure 2G-1 illustrates the "yaw plane.") From the standpoint of a tester facing a test port in a vertical stack, the yaw component of flow is the vector of flow moving to the left or right from the center of the stack as viewed by the tester. (This is sometimes referred to as "vortex flow," i.e., flow around the centerline of a stack or duct.) The yaw angle is the angle described by this yaw component of flow and the vertical axis of the stack. The algebraic sign convention is illustrated in Figure 2G-2.

3.24 Yaw Nulling. A procedure in which a Type-S pitot tube or a 3–D probe is rotated about its axis in a stack or duct until a zero differential pressure reading ('yaw null') is obtained. When a Type S probe is yawnulled, the rotational position of its impact port is 90° from the direction of flow in the stack or duct and the  $\Delta$  P reading is zero. When a 3–D probe is yaw-nulled, its impact pressure port (P<sub>1</sub>) faces directly into the direction of flow in the stack or duct and the differential pressure between pressure ports P<sub>2</sub> and P<sub>3</sub> is zero.

#### 4.0 Interferences. [Reserved]

### 5.0 Safety

5.1 This test method may involve hazardous operations and the use of hazardous materials or equipment. This method does not purport to address all of the safety problems associated with its use. It is the responsibility of the user to establish and implement appropriate safety and health practices and to determine the applicability of regulatory limitations before using this test method.

## 6.0 Equipment and Supplies

6.1 Two-dimensional Probes. Probes that provide both the velocity pressure and the vaw angle of the flow vector in a stack or duct, as listed in sections 6.1.1 and 6.1.2, qualify for use based on comprehensive wind funnel and field studies involving both interand intra-probe comparisons by multiple test teams. Each 2-D probe shall have a unique identification number or code permanently marked on the main probe sheath. Each probe shall be calibrated prior to use according to the procedures in section 10. Manufacturer-supplied calibration data shall be used as example information only, except when the manufacturer calibrates the probe as specified in section 10 and provides complete documentation.

6.1.1 Type S (Stausscheibe or reverse type) pitot tube. This is the same as specified in Method 2, section 2.1, except for the following additional specifications that enable the pitot tube to accurately determine the yaw component of flow. For the purposes of this method, the external diameter of the tubing used to construct the Type S pitot tube (dimension Dt in Figure 2-2 of Method 2) shall be no less than 9.5 mm (3/8 in.). The pitot tube shall also meet the following alignment specifications. The angles  $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$ , and  $\beta_2$ , as shown in Method 2, Figure 2-3, shall not exceed  $\pm 2^{\circ}$ . The dimensions *w* and z, shown in Method 2, Figure 2-3 shall not exceed 0.5 mm (0.02 in.).

6.1.1.1 Manual Type S probe. This refers to a Type S probe that is positioned at individual traverse points and yaw nulled manually by an operator.

6.1.1.2 Automated Type S probe. This refers to a system that uses a computer-controlled motorized mechanism to position the Type S pitot head at individual traverse points and perform yaw angle determinations.

6.1.2 Three-dimensional probes used in 2-D mode. A 3-D probe, as specified in sections 6.1.1 through 6.1.3 of Method 2F. may, for the purposes of this method, be used in a two-dimensional mode (i.e., measuring yaw angle, but not pitch angle). When the 3-D probe is used as a 2–D probe, only the velocity pressure and yaw-null pressure are obtained using the pressure taps referred to as  $P_1$ ,  $P_2$ , and  $P_3$ . The differential pressure  $P_1$ – $P_2$  is a function of total velocity and corresponds to the  $\Delta$  P obtained using the Type S probe. The differential pressure P2-P<sub>3</sub> is used to yaw null the probe and determine the yaw angle. The differential pressure P<sub>4</sub>–P<sub>5</sub>, which is a function of pitch angle, is not measured when the 3-D probe is used in 2-D mode.

6.1.3 Other probes. [Reserved]

6.1.4 Probe sheath. The probe shaft shall include an outer sheath to: (1) provide a surface for inscribing a permanent reference scribe line, (2) accommodate attachment of an angle-measuring device to the probe shaft, and (3) facilitate precise rotational movement of the probe for determining yaw angles. The sheath shall be rigidly attached to the probe assembly and shall enclose all pressure lines from the probe head to the farthest position away from the probe head where an angle-measuring device may be attached during use in the field. The sheath of the fully

assembled probe shall be sufficiently rigid and straight at all rotational positions such that, when one end of the probe shaft is held in a horizontal position, the fully extended probe meets the horizontal straightness specifications indicated in section 8.2 below.

6.1.5 Scribe lines.

6.1.5.1 Reference scribe line. A permanent line, no greater than 1.6 mm (1/ 16 in.) in width, shall be inscribed on each manual probe that will be used to determine yaw angles of flow. This line shall be placed on the main probe sheath in accordance with the procedures described in section 10.4 and is used as a reference position for installation of the yaw angle-measuring device on the probe. At the discretion of the tester, the scribe line may be a single line segment placed at a particular position on the probe sheath (e.g., near the probe head), multiple line segments placed at various locations along the length of the probe sheath (e.g., at every position where a yaw angle-measuring device may be mounted), or a single continuous line extending along the full length of the probe sheath.

6.1.5.2 Scribe line on probe extensions. A permanent line may also be inscribed on any probe extension that will be attached to the main probe in performing field testing. This allows a yaw angle-measuring device mounted on the extension to be readily aligned with the reference scribe line on the main probe sheath.

6.1.5.3 Alignment specifications. This specification shall be met separately, using the procedures in section 10.4.1, on the main probe and on each probe extension. The rotational position of the scribe line or scribe line segments on the main probe or any probe extension must not vary by more than  $2^{\circ}$ . That is, the difference between the minimum and maximum of all of the rotational angles that are measured along the full length of the main probe or the probe extension must not exceed  $2^{\circ}$ .

6.1.6 Probe and system characteristics to ensure horizontal stability.

6.1.6.1 For manual probes, it is recommended that the effective length of the probe (coupled with a probe extension, if necessary) be at least 0.9 m (3 ft.) longer than the farthest traverse point mark on the probe shaft away from the probe head. The operator should maintain the probe's horizontal stability when it is fully inserted into the stack or duct. If a shorter probe is used, the probe should be inserted through a bushing sleeve, similar to the one shown in Figure 2G-3, that is installed on the test port; such a bushing shall fit snugly around the probe and be secured to the stack or duct entry port in such a manner as to maintain the probe's horizontal stability when fully inserted into the stack or duct.

6.1.6.2 An automated system that includes an external probe casing with a transport system shall have a mechanism for maintaining horizontal stability comparable to that obtained by manual probes following the provisions of this method. The automated probe assembly shall also be constructed to maintain the alignment and position of the pressure ports during sampling at each traverse point. The design of the probe casing and transport system shall allow the probe to be removed from the stack or duct and checked through direct physical measurement for angular position and insertion depth.

6.1.7 The tubing that is used to connect the probe and the pressure-measuring device should have an inside diameter of at least 3.2 mm ( $\frac{1}{8}$  in.), to reduce the time required for pressure equilibration, and should be as short as practicable.

6.1.8 If a detachable probe head without a sheath [e.g., a pitot tube, typically 15.2 to 30.5 cm (6 to 12 in.) in length] is coupled with a probe sheath and calibrated in a wind tunnel in accordance with the yaw angle calibration procedure in section 10.5, the probe head shall remain attached to the probe sheath during field testing in the same configuration and orientation as calibrated. Once the detachable probe head is uncoupled or re-oriented, the yaw angle calibration of the probe is no longer valid and must be repeated before using the probe in subsequent field tests.

6.2 Yaw Angle-measuring Device. One of the following devices shall be used for measurement of the yaw angle of flow.

6.2.1 Digital inclinometer. This refers to a digital device capable of measuring and displaying the rotational position of the probe to within  $\pm 1^{\circ}$ . The device shall be able to be locked into position on the probe sheath or probe extension, so that it indicates the probe's rotational position throughout the test. A rotational position collar block that can be attached to the probe sheath (similar to the collar shown in Figure 2G–4) may be required to lock the digital inclinometer into position on the probe sheath.

6.2.2 Protractor wheel and pointer assembly. This apparatus, similar to that shown in Figure 2G–5, consists of the following components.

6.2.2.1 A protractor wheel that can be attached to a port opening and set in a fixed rotational position to indicate the yaw angle position of the probe's scribe line relative to the longitudinal axis of the stack or duct. The protractor wheel must have a measurement ring on its face that is no less than 17.8 cm (7 in.) in diameter, shall be able to be rotated to any angle and then locked into position on the stack or duct test port, and shall indicate angles to a resolution of 1°.

6.2.2.2 A pointer assembly that includes an indicator needle mounted on a collar that can slide over the probe sheath and be locked into a fixed rotational position on the probe sheath. The pointer needle shall be of sufficient length, rigidity, and sharpness to allow the tester to determine the probe's angular position to within 1° from the markings on the protractor wheel. Corresponding to the position of the pointer, the collar must have a scribe line to be used in aligning the pointer with the scribe line on the probe sheath.

6.2.3 Other yaw angle-measuring devices. Other angle-measuring devices with a manufacturer's specified precision of 1° or better may be used, if approved by the Administrator.

6.3 Probe Supports and Stabilization Devices. When probes are used for determining flow angles, the probe head should be kept in a stable horizontal position. For probes longer than 3.0 m (10 ft.), the section of the probe that extends outside the test port shall be secured. Three alternative devices are suggested for maintaining the horizontal position and stability of the probe shaft during flow angle determinations and velocity pressure measurements: (1) monorails installed above each port, (2) probe stands on which the probe shaft may be rested, or (3) bushing sleeves of sufficient length secured to the test ports to maintain probes in a horizontal position. Comparable provisions shall be made to ensure that automated systems maintain the horizontal position of the probe in the stack or duct. The physical characteristics of each test platform may dictate the most suitable type of stabilization device. Thus, the choice of a specific stabilization device is left to the judgement of the testers.

6.4 Differential Pressure Gauges. The velocity pressure ( $\Delta$  P) measuring devices used during wind tunnel calibrations and field testing shall be either electronic manometers (e.g., pressure transducers), fluid manometers, or mechanical pressure gauges (e.g., Magnehelic<sup>®</sup> gauges). Use of electronic manometers is recommended. Under low velocity conditions, use of electronic manometers may be necessary to obtain acceptable measurements.

6.4.1 Differential pressure-measuring device. This refers to a device capable of measuring pressure differentials and having a readability of  $\pm 1$  percent of full scale. The device shall be capable of accurately measuring the maximum expected pressure differential. Such devices are used to determine the following pressure measurements: velocity pressure, static pressure, and yaw-null pressure. For an inclined-vertical manometer, the readability specification of ±1 percent shall be met separately using the respective full-scale upper limits of the inclined and vertical portions of the scales. To the extent practicable, the device shall be selected such that most of the pressure readings are between 10 and 90 percent of the device's full-scale measurement range (as defined in section 3.4). In addition, pressure-measuring devices should be selected such that the zero does not drift by more than 5 percent of the average expected pressure readings to be encountered during the field test. This is particularly important under low pressure conditions

6.4.2 Gauge used for yaw nulling. The differential pressure-measuring device chosen for yaw nulling the probe during the wind tunnel calibrations and field testing shall be bi-directional, i.e., capable of reading both positive and negative differential pressures. If a mechanical, bi-directional pressure gauge is chosen, it shall have a full-scale range no greater than 2.6 cm (i.e., -1.3 to +1.3 cm) [1 in. H<sub>2</sub>O (i.e., -0.5 in. to +0.5 in.)].

6.4.3 Devices for calibrating differential pressure-measuring devices. A precision manometer (e.g., a U-tube, inclined, or inclined-vertical manometer, or micromanometer) or NIST (National Institute of Standards and Technology) traceable pressure source shall be used for calibrating differential pressure-measuring devices. The device shall be maintained under laboratory conditions or in a similar protected environment (e.g., a climate-controlled trailer). It shall not be used in field tests. The precision manometer shall have a scale gradation of 0.3 mm  $H_2O$  (0.01 in.  $H_2O$ ), or less, in the range of 0 to 5.1 cm  $H_2O$  (0 to 2 in.  $H_2O$ ) and 2.5 mm  $H_2O$  (0.1 in.  $H_2O$ ), or less, in the range of 5.1 to 25.4 cm  $H_2O$  (2 to 10 in.  $H_2O$ ). The manometer shall have manufacturer's documentation that it meets an accuracy specification of at least 0.5 percent of full scale. The NIST-traceable pressure source shall be recertified annually.

6.4.4 Devices used for post-test calibration check. A precision manometer meeting the specifications in section 6.4.3, a pressure-measuring device or pressure source with a documented calibration traceable to NIST, or an equivalent device approved by the Administrator shall be used for the posttest calibration check. The pressure measuring device shall have a readability equivalent to or greater than the tested device. The pressure source shall be capable of generating pressures between 50 and 90 percent of the range of the tested device and known to within  $\pm 1$  percent of the full scale of the tested device. The pressure source shall be recertified annually.

6.5 Data Display and Capture Devices. Electronic manometers (if used) shall be coupled with a data display device (such as a digital panel meter, personal computer display, or strip chart) that allows the tester to observe and validate the pressure measurements taken during testing. They shall also be connected to a data recorder (such as a data logger or a personal computer with data capture software) that has the ability to compute and retain the appropriate average value at each traverse point, identified by collection time and traverse point.

6.6 Temperature Gauges. For field tests, a thermocouple or resistance temperature detector (RTD) capable of measuring temperature to within  $\pm 3^{\circ}C$  ( $\pm 5^{\circ}F$ ) of the stack or duct temperature shall be used. The thermocouple shall be attached to the probe such that the sensor tip does not touch any metal. The position of the thermocouple relative to the pressure port face openings shall be in the same configuration as used for the probe calibrations in the wind tunnel. Temperature gauges used for wind tunnel calibrations shall be capable of measuring temperature to within  $\pm 0.6^{\circ}$ C ( $\pm 1^{\circ}$ F) of the temperature of the flowing gas stream in the wind tunnel.

6.7 Stack or Duct Static Pressure Measurement. The pressure-measuring device used with the probe shall be as specified in section 6.4 of this method. The static tap of a standard (Prandtl type) pitot tube or one leg of a Type S pitot tube with the face opening planes positioned parallel to the gas flow may be used for this measurement. Also acceptable is the pressure differential reading of P<sub>1</sub>-P<sub>bar</sub> from a five-hole prism-shaped 3–D probe, as specified in section 6.1.1 of Method 2F (such as the Type DA or DAT probe), with the P<sub>1</sub> pressure port face opening positioned parallel to the gas flow in the same manner as the Type S probe. However, the 3–D spherical probe, as specified in section 6.1.2 of Method 2F, is unable to provide this measurement and shall not be used to take static pressure measurements. Static pressure measurement is further described in section 8.11.

6.8 Barometer. Same as Method 2, section 2.5.

6.9 Gas Density Determination Equipment. Method 3 or 3A shall be used to determine the dry molecular weight of the stack or duct gas. Method 4 shall be used for moisture content determination and computation of stack or duct gas wet molecular weight. Other methods may be used, if approved by the Administrator.

6.10 Calibration Pitot Tube. Same as Method 2, section 2.7.

6.11 Wind Tunnel for Probe Calibration. Wind tunnels used to calibrate velocity probes must meet the following design specifications.

6.11.1 Test section cross-sectional area. The flowing gas stream shall be confined within a circular, rectangular, or elliptical duct. The cross-sectional area of the tunnel must be large enough to ensure fully developed flow in the presence of both the calibration pitot tube and the tested probe. The calibration site, or "test section," of the wind tunnel shall have a minimum diameter of 30.5 cm (12 in.) for circular or elliptical duct cross-sections or a minimum width of 30.5 cm (12 in.) on the shorter side for rectangular cross-sections. Wind tunnels shall meet the probe blockage provisions of this section and the qualification requirements prescribed in section 10.1. The projected area of the portion of the probe head, shaft, and attached devices inside the wind tunnel during calibration shall represent no more than 4 percent of the cross-sectional area of the tunnel. The projected area shall include the combined area of the calibration pitot tube and the tested probe if both probes are placed simultaneously in the same cross-sectional plane in the wind tunnel, or the larger projected area of the two probes if they are placed alternately in the wind tunnel.

6.11.2 Velocity range and stability. The wind tunnel should be capable of maintaining velocities between 6.1 m/sec and 30.5 m/sec (20 ft/sec and 100 ft/sec). The wind tunnel shall produce fully developed flow patterns that are stable and parallel to the axis of the duct in the test section.

6.11.3 Flow profile at the calibration location. The wind tunnel shall provide axial flow within the test section calibration location (as defined in section 3.21). Yaw and pitch angles in the calibration location shall be within  $\pm 3^{\circ}$  of 0°. The procedure for determining that this requirement has been met is described in section 10.1.2.

6.11.4 Entry ports in the wind tunnel test section.

6.11.4.1 Port for tested probe. A port shall be constructed for the tested probe. This port shall be located to allow the head of the tested probe to be positioned within the wind tunnel calibration location (as defined in section 3.21). The tested probe shall be able to be locked into the 0° pitch angle position. To facilitate alignment of the probe during calibration, the test section should include a

window constructed of a transparent material to allow the tested probe to be viewed.

6.11.4.2 Port for verification of axial flow. Depending on the equipment selected to conduct the axial flow verification prescribed in section 10.1.2, a second port, located  $90^{\circ}$  from the entry port for the tested probe, may be needed to allow verification that the gas flow is parallel to the central axis of the test section. This port should be located and constructed so as to allow one of the probes described in section 10.1.2.2 to access the same test point(s) that are accessible from the port described in section 6.11.4.1.

6.11.4.3 Port for calibration pitot tube. The calibration pitot tube shall be used in the port for the tested probe or in a separate entry port. In either case, all measurements with the calibration pitot tube shall be made at the same point within the wind tunnel over the course of a probe calibration. The measurement point for the calibration pitot tube shall meet the same specifications for distance from the wall and for axial flow as described in section 3.21 for the wind tunnel calibration location.

## 7.0 Reagents and Standards. [Reserved]

## 8.0 Sample Collection and Analysis

8.1 Equipment Inspection and Set Up

8.1.1 All 2–D and 3–D probes, differential pressure-measuring devices, yaw anglemeasuring devices, thermocouples, and barometers shall have a current, valid calibration before being used in a field test. (See sections 10.3.3, 10.3.4, and 10.5 through 10.10 for the applicable calibration requirements.)

8.1.2 Before each field use of a Type S probe, perform a visual inspection to verify the physical condition of the pitot tube. Record the results of the inspection. If the face openings are noticeably misaligned or there is visible damage to the face openings, the probe shall not be used until repaired, the dimensional specifications verified (according to the procedures in section 10.2.1), and the probe recalibrated.

8.1.3 Before each field use of a 3–D probe, perform a visual inspection to verify the physical condition of the probe head according to the procedures in section 10.2 of Method 2F. Record the inspection results on a form similar to Table 2F–1 presented in Method 2F. If there is visible damage to the 3–D probe, the probe shall not be used until it is recalibrated.

8.1.4 After verifying that the physical condition of the probe head is acceptable, set up the apparatus using lengths of flexible tubing that are as short as practicable. Surge tanks installed between the probe and pressure-measuring device may be used to dampen pressure fluctuations provided that an adequate measurement system response time (see section 8.8) is maintained.

8.2 Horizontal Straightness Check. A horizontal straightness check shall be performed before the start of each field test, except as otherwise specified in this section. Secure the fully assembled probe (including the probe head and all probe shaft extensions) in a horizontal position using a stationary support at a point along the probe shaft approximating the location of the stack

or duct entry port when the probe is sampling at the farthest traverse point from the stack or duct wall. The probe shall be rotated to detect bends. Use an anglemeasuring device or trigonometry to determine the bend or sag between the probe head and the secured end. (See Figure 2G-6.) Probes that are bent or sag by more than 5° shall not be used. Although this check does not apply when the probe is used for a vertical traverse, care should be taken to avoid the use of bent probes when conducting vertical traverses. If the probe is constructed of a rigid steel material and consists of a main probe without probe extensions, this check need only be performed before the initial field use of the probe, when the probe is recalibrated, when a change is made to the design or material of the probe assembly, and when the probe becomes bent. With such probes, a visual inspection shall be made of the fully assembled probe before each field test to determine if a bend is visible. The probe shall be rotated to detect bends. The inspection results shall be documented in the field test report. If a bend in the probe is visible, the horizontal straightness check shall be performed before the probe is used.

8.3 Rotational Position Check. Before each field test, and each time an extension is added to the probe during a field test, a rotational position check shall be performed on all manually operated probes (except as noted in section 8.3.5 below) to ensure that, throughout testing, the angle-measuring device is either: aligned to within  $\pm 1^{\circ}$  of the rotational position of the reference scribe line; or is affixed to the probe such that the rotational offset of the device from the reference scribe line is known to within  $\pm 1^{\circ}$ . This check shall consist of direct measurements of the rotational positions of the reference scribe line and angle-measuring device sufficient to verify that these specifications are met. Annex A in section 18 of this method gives recommended procedures for performing the rotational position check, and Table 2G-2 gives an example data form. Procedures other than those recommended in Annex A in section 18 may be used, provided they demonstrate whether the alignment specification is met and are explained in detail in the field test report.

8.3.1 Angle-measuring device rotational offset. The tester shall maintain a record of the angle-measuring device rotational offset,  $R_{ADO}$ , as defined in section 3.1. Note that  $R_{ADO}$  is assigned a value of 0° when the angle-measuring device is aligned to within  $\pm 1^{\circ}$  of the rotational position of the reference scribe line. The  $R_{ADO}$  shall be used to determine the yaw angle of flow in accordance with section 8.9.4.

8.3.2 Sign of angle-measuring device rotational offset. The sign of  $R_{ADO}$  is positive when the angle-measuring device (as viewed from the "tail" end of the probe) is positioned in a clockwise direction from the reference scribe line and negative when the device is positioned in a counterclockwise direction from the reference scribe line.

**8.3.3** Angle-measuring devices that can be independently adjusted (e.g., by means of a set screw), after being locked into position

on the probe sheath, may be used. However, the  $R_{\rm ADO}$  must also take into account this adjustment.

8.3.4 Post-test check. If probe extensions remain attached to the main probe throughout the field test, the rotational position check shall be repeated, at a minimum, at the completion of the field test to ensure that the angle-measuring device has remained within  $\pm 2^{\circ}$  of its rotational position established prior to testing. At the discretion of the tester, additional checks may be conducted after completion of testing at any sample port or after any test run. If the  $\pm 2$ specification is not met, all measurements made since the last successful rotational position check must be repeated. Section 18.1.1.3 of Annex A provides an example procedure for performing the post-test check. 8.3.5 Exceptions.

8.3.5.1 A rotational position check need not be performed if, for measurements taken at all velocity traverse points, the yaw anglemeasuring device is mounted and aligned directly on the reference scribe line specified in sections 6.1.5.1 and 6.1.5.3 and no independent adjustments, as described in section 8.3.3, are made to device's rotational position.

8.3.5.2 If extensions are detached and reattached to the probe during a field test, a rotational position check need only be performed the first time an extension is added to the probe, rather than each time the extension is re-attached, if the probe extension is designed to be locked into a mechanically fixed rotational position (e.g., through the use of interlocking grooves), that can re-establish the initial rotational position to within  $\pm 1^{\circ}$ .

8.4 Leak Checks. A pre-test leak check shall be conducted before each field test. A post-test check shall be performed at the end of the field test, but additional leak checks may be conducted after any test run or group of test runs. The post-test check may also serve as the pre-test check for the next group of test runs. If any leak check is failed, all runs since the last passed leak check are invalid. While performing the leak check procedures, also check each pressure device's responsiveness to changes in pressure.

8.4.1 To perform the leak check on a Type S pitot tube, pressurize the pitot impact opening until at least 7.6 cm H<sub>2</sub>O (3 in. H<sub>2</sub>O) velocity pressure, or a pressure corresponding to approximately 75 percent of the pressure device's measurement scale, whichever is less, registers on the pressure device; then, close off the impact opening. The pressure shall remain stable ( $\pm$ 2.5 mm H<sub>2</sub>O,  $\pm$ 0.10 in. H<sub>2</sub>O) for at least 15 seconds. Repeat this procedure for the static pressure side, except use suction to obtain the required pressure. Other leak-check procedures may be used, if approved by the Administrator.

8.4.2 To perform the leak check on a 3– D probe, pressurize the probe's impact ( $P_1$ ) opening until at least 7.6 cm  $H_2O$  (3 in.  $H_2O$ ) velocity pressure, or a pressure corresponding to approximately 75 percent of the pressure device's measurement scale, whichever is less, registers on the pressure device; then, close off the impact opening. The pressure shall remain stable (±2.5 mm 26528

 $H_2O$ ,  $\pm 0.10$  in.  $H_2O$ ) for at least 15 seconds. Check the  $P_2$  and  $P_3$  pressure ports in the same fashion. Other leak-check procedures may be used, if approved by the Administrator.

8.5 Zeroing the Differential Pressuremeasuring Device. Zero each differential pressure-measuring device, including the device used for yaw nulling, before each field test. At a minimum, check the zero after each field test. A zero check may also be performed after any test run or group of test runs. For fluid manometers and mechanical pressure gauges (e.g., Magnehelic® gauges), the zero reading shall not deviate from zero by more than  $\pm 0.8$  mm H<sub>2</sub>O ( $\pm 0.03$  in. H<sub>2</sub>O) or one minor scale division, whichever is greater, between checks. For electronic manometers, the zero reading shall not deviate from zero between checks by more than:  $\pm 0.3$  mm H<sub>2</sub>O ( $\pm 0.01$  in. H<sub>2</sub>O), for full scales less than or equal to 5.1 cm H<sub>2</sub>O (2.0 in. H<sub>2</sub>O); or ±0.8 mm H<sub>2</sub>O (±0.03 in. H<sub>2</sub>O), for full scales greater than 5.1 cm H<sub>2</sub>O (2.0 in. H<sub>2</sub>O). (Note: If negative zero drift is not directly readable, estimate the reading based on the position of the gauge oil in the manometer or of the needle on the pressure gauge.) In addition, for all pressuremeasuring devices except those used exclusively for yaw nulling, the zero reading shall not deviate from zero by more than 5 percent of the average measured differential pressure at any distinct process condition or load level. If any zero check is failed at a specific process condition or load level, all runs conducted at that process condition or load level since the last passed zero check are invalid.

8.6 Traverse Point Verification. The number and location of the traverse points shall be selected based on Method 1 guidelines. The stack or duct diameter and port nipple lengths, including any extension of the port nipples into the stack or duct, shall be verified the first time the test is performed; retain and use this information for subsequent field tests, updating it as required. Physically measure the stack or duct dimensions or use a calibrated laser device; do not use engineering drawings of the stack or duct. The probe length necessary to reach each traverse point shall be recorded to within  $\pm 6.4$  mm ( $\pm 1/4$  in.) and, for manual probes, marked on the probe sheath. In determining these lengths, the tester shall take into account both the distance that the port flange projects outside of the stack and the depth that any port nipple extends into the gas stream. The resulting point positions shall reflect the true distances from the inside wall of the stack or duct, so that when the tester aligns any of the markings with the outside face of the stack port, the probe's impact port shall be located at the appropriate distance from the inside wall for the respective Method 1 traverse point. Before beginning testing at a particular location, an out-of-stack or duct verification shall be performed on each probe that will be used to ensure that these position markings are correct. The distances measured during the verification must agree with the previously calculated distances to within  $\pm \frac{1}{4}$ in. For manual probes, the traverse point positions shall be verified by measuring the

distance of each mark from the probe's impact pressure port (the  $P_1$  port for a 3-D probe). A comparable out-of-stack test shall be performed on automated probe systems. The probe shall be extended to each of the prescribed traverse point positions. Then, the accuracy of the positioning for each traverse point shall be verified by measuring the distance between the port flange and the probe's impact pressure port.

8.7 Probe Installation. Insert the probe into the test port. A solid material shall be used to seal the port.

8.8 System Response Time. Determine the response time of the probe measurement system. Insert and position the "cold" probe (at ambient temperature and pressure) at any Method 1 traverse point. Read and record the probe differential pressure, temperature, and elapsed time at 15-second intervals until stable readings for both pressure and temperature are achieved. The response time is the longer of these two elapsed times. Record the response time.

8.9 Sampling.

8.9.1 Yaw angle measurement protocol. With manual probes, yaw angle measurements may be obtained in two alternative ways during the field test, either by using a yaw angle-measuring device (e.g., digital inclinometer) affixed to the probe, or using a protractor wheel and pointer assembly. For horizontal traversing, either approach may be used. For vertical traversing, i.e., when measuring from on top or into the bottom of a horizontal duct, only the protractor wheel and pointer assembly may be used. With automated probes, curvefitting protocols may be used to obtain yawangle measurements.

8.9.1.1 If a yaw angle-measuring device affixed to the probe is to be used, lock the device on the probe sheath, aligning it either on the reference scribe line or in the rotational offset position established under section 8.3.1.

**8.9.1.2** If a protractor wheel and pointer assembly is to be used, follow the procedures in Annex B of this method.

8.9.1.3 Curve-fitting procedures. Curvefitting routines sweep through a range of yaw angles to create curves correlating pressure to yaw position. To find the zero yaw position and the yaw angle of flow, the curve found in the stack is computationally compared to a similar curve that was previously generated under controlled conditions in a wind tunnel. A probe system that uses a curvefitting routine for determining the yaw-null position of the probe head may be used, provided that it is verified in a wind tunnel to be able to determine the yaw angle of flow to within  $\pm 1^{\circ}$ .

8.9.1.4 Other yaw angle determination procedures. If approved by the Administrator, other procedures for determining yaw angle may be used, provided that they are verified in a wind tunnel to be able to perform the yaw angle calibration procedure as described in section 10.5.

8.9.2 Sampling strategy. At each traverse point, first yaw-null the probe, as described in section 8.9.3, below. Then, with the probe oriented into the direction of flow, measure and record the yaw angle, the differential

pressure and the temperature at the traverse point, after stable readings are achieved, in accordance with sections 8.9.4 and 8.9.5. At the start of testing in each port (i.e., after a probe has been inserted into the flue gas stream), allow at least the response time to elapse before beginning to take measurements at the first traverse point accessed from that port. Provided that the probe is not removed from the flue gas stream, measurements may be taken at subsequent traverse points accessed from the same test port without waiting again for the response time to elapse.

8.9.3 Yaw-nulling procedure. In preparation for yaw angle determination, the probe must first be yaw nulled. After positioning the probe at the appropriate traverse point, perform the following procedures.

8.9.3.1 For Type S probes, rotate the probe until a null differential pressure reading is obtained. The direction of the probe rotation shall be such that the thermocouple is located downstream of the probe pressure ports at the yaw-null position. Rotate the probe  $90^{\circ}$  back from the yaw-null position to orient the impact pressure port into the direction of flow. Read and record the angle displayed by the angle-measuring device.

8.9.3.2 For 3-D probes, rotate the probe until a null differential pressure reading (the difference in pressures across the  $P_2$  and  $P_3$ pressure ports is zero, i.e.,  $P_2 = P_3$ ) is indicated by the yaw angle pressure gauge. Read and record the angle displayed by the angle-measuring device.

8.9.3.3 Sign of the measured angle. The angle displayed on the angle-measuring device is considered positive when the probe's impact pressure port (as viewed from the "tail" end of the probe) is oriented in a clockwise rotational position relative to the stack or duct axis and is considered negative when the probe's impact pressure port is oriented in a counterclockwise rotational position (see Figure 2G–7).

8.9.4 Yaw angle determination. After performing the applicable yaw-nulling procedure in section 8.9.3, determine the yaw angle of flow according to one of the following procedures. Special care must be observed to take into account the signs of the recorded angle reading and all offsets.

8.9.4.1 Direct-reading. If all rotational offsets are zero or if the angle-measuring device rotational offset ( $R_{ADO}$ ) determined in section 8.3 exactly compensates for the scribe line rotational offset ( $R_{SLO}$ ) determined in section 10.5, then the magnitude of the yaw angle is equal to the displayed angle-measuring device reading from section 8.9.3.1 or 8.9.3.2. The algebraic sign of the yaw angle is determined in accordance with section 8.9.3.3. [Note: Under certain circumstances (e.g., testing of horizontal ducts) a 90° adjustment to the angle-measuring device readings may be necessary to obtain the correct yaw angles.]

8.9.4.2 Compensation for rotational offsets during data reduction. When the angle-measuring device rotational offset does not compensate for reference scribe line rotational offset, the following procedure shall be used to determine the yaw angle:

(a) Enter the reading indicated by the angle-measuring device from section 8.9.3.1 or 8.9.3.2.

(b) Associate the proper algebraic sign from section 8.9.3.3 with the reading in step (a).

(c) Subtract the reference scribe line rotational offset,  $R_{SLO}$ , from the reading in

step (b). (d) Subtract the angle-measuring device rotational offset,  $R_{ADO}$ , if any, from the result obtained in step (c).

(e) The final result obtained in step (d) is the yaw angle of flow.

[**Note:** It may be necessary to first apply a  $90^{\circ}$  adjustment to the reading in step (a), in order to obtain the correct yaw angle.]

8.9.4.3 Record the yaw angle measurements on a form similar to Table 2G–3.

8.9.5 Impact velocity determination. Maintain the probe rotational position established during the yaw angle determination. Then, begin recording the pressure-measuring device readings. These pressure measurements shall be taken over a sampling period of sufficiently long duration to ensure representative readings at each traverse point. If the pressure measurements are determined from visual readings of the pressure device or display, allow sufficient time to observe the pulsation in the readings to obtain a sight-weighted average, which is then recorded manually. If an automated data acquisition system (e.g., data logger, computer-based data recorder, strip chart recorder) is used to record the pressure measurements, obtain an integrated average of all pressure readings at the traverse point. Stack or duct gas temperature measurements shall be recorded, at a minimum, once at each traverse point. Record all necessary data as shown in the example field data form (Table 2G-3).

8.9.6 Alignment check. For manually operated probes, after the required yaw angle and differential pressure and temperature measurements have been made at each traverse point, verify (e.g., by visual inspection) that the yaw angle-measuring device has remained in proper alignment with the reference scribe line or with the rotational offset position established in section 8.3. If, for a particular traverse point, the angle-measuring device is found to be in proper alignment, proceed to the next traverse point; otherwise, re-align the device and repeat the angle and differential pressure measurements at the traverse point. In the course of a traverse, if a mark used to properly align the angle-measuring device (e.g., as described in section 18.1.1.1) cannot be located, re-establish the alignment mark before proceeding with the traverse.

8.10 Probe Plugging. Periodically check for plugging of the pressure ports by observing the responses on the pressure differential readouts. Plugging causes erratic results or sluggish responses. Rotate the probe to determine whether the readouts respond in the expected direction. If plugging is detected, correct the problem and repeat the affected measurements.

8.11 Static Pressure. Measure the static pressure in the stack or duct using the equipment described in section 6.7.

8.11.1 If a Type S probe is used for this measurement, position the probe at or between any traverse point(s) and rotate the probe until a null differential pressure reading is obtained. Disconnect the tubing from one of the pressure ports; read and record the  $\Delta$  P. For pressure devices with one-directional scales, if a deflection in the positive direction is noted with the negative side disconnected, then the static pressure is positive. Likewise, if a deflection in the positive direction is noted with the positive side disconnected, then the static pressure is negative.

**8**.11.2 If a 3–D probe is used for this measurement, position the probe at or between any traverse point(s) and rotate the probe until a null differential pressure reading is obtained at  $P_2$ – $P_3$ . Rotate the probe 90°. Disconnect the  $P_2$  pressure side of the probe and read the pressure  $P_1$ – $P_{bar}$  and record as the static pressure. (**Note:** The spherical probe, specified in section 6.1.2 of Method 2F, is unable to provide this measurement and shall not be used to take static pressure measurements.)

8.12 Atmospheric Pressure. Determine the atmospheric pressure at the sampling elevation during each test run following the procedure described in section 2.5 of Method 2

8.13 Molecular Weight. Determine the stack or duct gas dry molecular weight. For combustion processes or processes that emit essentially  $CO_2$ ,  $O_2$ , CO, and  $N_2$ , use Method 3 or 3A. For processes emitting essentially air, an analysis need not be conducted; use a dry molecular weight of 29.0. Other methods may be used, if approved by the Administrator.

8.14 Moisture. Determine the moisture content of the stack gas using Method 4 or equivalent.

8.15 Data Recording and Calculations. Record all required data on a form similar to Table 2G–3.

8.15.1 2–D probe calibration coefficient. When a Type S pitot tube is used in the field, the appropriate calibration coefficient as determined in section 10.6 shall be used to perform velocity calculations. For calibrated Type S pitot tubes, the A-side coefficient shall be used when the A-side of the tube faces the flow, and the B-side faces the flow.

8.15.2 3–D calibration coefficient. When a 3–D probe is used to collect data with this method, follow the provisions for the calibration of 3–D probes in section 10.6 of Method 2F to obtain the appropriate velocity calibration coefficient ( $F_2$  as derived using Equation 2F–2 in Method 2F) corresponding to a pitch angle position of 0°.

8.15.3 Calculations. Calculate the yawadjusted velocity at each traverse point using the equations presented in section 12.2. Calculate the test run average stack gas velocity by finding the arithmetic average of the point velocity results in accordance with sections 12.3 and 12.4, and calculate the stack gas volumetric flow rate in accordance with section 12.5 or 12.6, as applicable.

## 9.0 Quality Control

9.1 Quality Control Activities. In conjunction with the yaw angle

determination and the pressure and temperature measurements specified in section 8.9, the following quality control checks should be performed.

9.1.1 Range of the differential pressure gauge. In accordance with the specifications in section 6.4, ensure that the proper differential pressure gauge is being used for the range of  $\Delta$  P values encountered. If it is necessary to change to a more sensitive gauge, replace the gauge with a gauge calibrated according to section 10.3.3, perform the leak check described in section 8.4 and the zero check described in section 8.5, and repeat the differential pressure and temperature readings at each traverse point.

9.1.2 Horizontal stability check. For horizontal traverses of a stack or duct, visually check that the probe shaft is maintained in a horizontal position prior to taking a pressure reading. Periodically, during a test run, the probe's horizontal stability should be verified by placing a carpenter's level, a digital inclinometer, or other angle-measuring device on the portion of the probe sheath that extends outside of the test port. A comparable check should be performed by automated systems.

## 10.0 Calibration

10.1 Wind Tunnel Qualification Checks. To qualify for use in calibrating probes, a wind tunnel shall have the design features specified in section 6.11 and satisfy the following qualification criteria. The velocity pressure cross-check in section 10.1.1 and axial flow verification in section 10.1.2 shall be performed before the initial use of the wind tunnel and repeated immediately after any alteration occurs in the wind tunnel's configuration, fans, interior surfaces, straightening vanes, controls, or other properties that could reasonably be expected to alter the flow pattern or velocity stability in the tunnel. The owner or operator of a wind tunnel used to calibrate probes according to this method shall maintain records documenting that the wind tunnel meets the requirements of sections 10.1.1 and 10.1.2 and shall provide these records to the Administrator upon request.

10.1.1 Velocity pressure cross-check. To verify that the wind tunnel produces the same velocity at the tested probe head as at the calibration pitot tube impact port perform the following cross-check. Take three differential pressure measurements at the fixed calibration pitot tube location, using the calibration pitot tube specified in section 6.10, and take three measurements with the calibration pitot tube at the wind tunnel calibration location, as defined in section 3.21. Alternate the measurements between the two positions. Perform this procedure at the lowest and highest velocity settings at which the probes will be calibrated. Record the values on a form similar to Table 2G-4. At each velocity setting, the average velocity pressure obtained at the wind tunnel calibration location shall be within ±2 percent or 2.5 mm  $H_2O$  (0.01 in.  $H_2O$ ), whichever is less restrictive, of the average velocity pressure obtained at the fixed calibration pitot tube location. This comparative check shall be performed at 2.5-cm (1-in.), or smaller,

intervals across the full length, width, and depth (if applicable) of the wind tunnel calibration location. If the criteria are not met at every tested point, the wind tunnel calibration location must be redefined, so that acceptable results are obtained at every point. Include the results of the velocity pressure cross-check in the calibration data section of the field test report. (See section 16.1.4.)

10.1.2 Axial flow verification. The following procedures shall be performed to demonstrate that there is fully developed axial flow within the wind tunnel calibration location and at the calibration pitot tube location. Two options are available to conduct this check.

10.1.2.1 Using a calibrated 3-D probe. A probe that has been previously calibrated in a wind tunnel with documented axial flow (as defined in section 3.22) may be used to conduct this check. Insert the calibrated 3-D probe into the wind tunnel test section using the tested probe port. Following the procedures in sections 8.9 and 12.2 of Method 2F, determine the yaw and pitch angles at all the point(s) in the test section where the velocity pressure cross-check, as specified in section 10.1.1, is performed. This includes all the points in the calibration location and the point where the calibration pitot tube will be located. Determine the yaw and pitch angles at each point. Repeat these measurements at the highest and lowest velocities at which the probes will be calibrated. Record the values on a form similar to Table 2G-5. Each measured yaw and pitch angle shall be within  $\pm 3^{\circ}$  of  $0^{\circ}$ . Exceeding the limits indicates unacceptable flow in the test section. Until the problem is corrected and acceptable flow is verified by repetition of this procedure, the wind tunnel shall not be used for calibration of probes. Include the results of the axial flow verification in the calibration data section of the field test report. (See section 16.1.4.)

10.1.2.2 Using alternative probes. Axial flow verification may be performed using an uncalibrated prism-shaped 3-D probe (e.g. DA or DAT probe) or an uncalibrated wedge probe. (Figure 2G-8 illustrates a typical wedge probe.) This approach requires use of two ports: the tested probe port and a second port located 90° from the tested probe port. Each port shall provide access to all the points within the wind tunnel test section where the velocity pressure cross-check, as specified in section 10.1.1, is conducted. The probe setup shall include establishing a reference yaw-null position on the probe sheath to serve as the location for installing the angle-measuring device. Physical design features of the DA, DAT, and wedge probes are relied on to determine the reference position. For the DA or DAT probe, this reference position can be determined by setting a digital inclinometer on the flat facet where the  $P_1$  pressure port is located and then identifying the rotational position on the probe sheath where a second angle measuring device would give the same angle reading. The reference position on a wedge probe shaft can be determined either geometrically or by placing a digital inclinometer on each side of the wedge and rotating the probe until equivalent readings

are obtained. With the latter approach, the reference position is the rotational position on the probe sheath where an angle measuring device would give a reading of 0°. After installation of the angle-measuring device in the reference yaw-null position on the probe sheath, determine the yaw angle from the tested port. Repeat this measurement using the 90° offset port, which provides the pitch angle of flow. Determine the yaw and pitch angles at all the point(s) in the test section where the velocity pressure cross-check, as specified in section 10.1.1, is performed. This includes all the points in the wind tunnel calibration location and the point where the calibration pitot tube will be located. Perform this check at the highest and lowest velocities at which the probes will be calibrated. Record the values on a form similar to Table 2G-5. Each measured yaw and pitch angle shall be within  $\pm 3^{\circ}$  of  $0^{\circ}$ . Exceeding the limits indicates unacceptable flow in the test section. Until the problem is corrected and acceptable flow is verified by repetition of this procedure, the wind tunnel shall not be used for calibration of probes. Include the results in the probe calibration report.

10.1.3 Wind tunnel audits. 10.1.3.1 Procedure. Upon the request of the Administrator, the owner or operator of a wind tunnel shall calibrate a 2-D audit probe in accordance with the procedures described in sections 10.3 through 10.6. The calibration shall be performed at two velocities that encompass the velocities typically used for this method at the facility. The resulting calibration data shall be submitted to the Agency in an audit test report. These results shall be compared by the Agency to reference calibrations of the audit probe at the same velocity settings obtained at two different wind tunnels.

10.1.3.2 Acceptance criterion. The audited tunnel's calibration coefficient is acceptable if it is within 3 percent of the reference calibrations obtained at each velocity setting by one (or both) of the wind tunnels. If the acceptance criterion is not met at each calibration velocity setting, the audited wind tunnel shall not be used to calibrate probes for use under this method until the problems are resolved and acceptable results are obtained upon completion of a subsequent audit.

10.2 Probe Inspection.

10.2.1 Type S probe. Before each calibration of a Type S probe, verify that one leg of the tube is permanently marked A, and the other, B. Carefully examine the pitot tube from the top, side, and ends. Measure the angles ( $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$ , and  $\beta_2$ ) and the dimensions (w and z) illustrated in Figures 2-2 and 2-3 in Method 2. Also measure the dimension A, as shown in the diagram in Table 2G-1, and the external tubing diameter (dimension D<sub>t</sub>, Figure 2–2b in Method 2). For the purposes of this method, Dt shall be no less than 9.5 mm (3/8 in.). The base-to-opening plane distances P<sub>A</sub> and P<sub>B</sub> in Figure 2–3 of Method 2 shall be equal, and the dimension A in Table 2G-1 should be between 2.10Dt and 3.00Dt. Record the inspection findings and probe measurements on a form similar to Table CD2–1 of the "Quality Assurance Handbook for Air Pollution Measurement

Systems: Volume III, Stationary Source-Specific Methods' (EPA/600/R-94/038c, September 1994). For reference, this form is reproduced herein as Table 2G-1. The pitot tube shall not be used under this method if it fails to meet the specifications in this section and the alignment specifications in section 6.1.1. All Type S probes used to collect data with this method shall be calibrated according to the procedures outlined in sections 10.3 through 10.6 below. During calibration, each Type S pitot tube shall be configured in the same manner as used, or planned to be used, during the field test, including all components in the probe assembly (e.g., thermocouple, probe sheath, sampling nozzle). Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration. 10.2.2 3-D probe. If a 3-D probe is used to collect data with this method, perform the pre-calibration inspection according to procedures in Method 2F, section 10.2. 10.3 Pre-Calibration Procedures. Prior to calibration, a scribe line shall have been placed on the probe in accordance with section 10.4. The yaw angle and velocity calibration procedures shall not begin until the pre-test requirements in sections 10.3.1 through 10.3.4 have been met.

10.3.1 Perform the horizontal straightness check described in section 8.2 on the probe assembly that will be calibrated in the wind tunnel.

10.3.2 Perform a leak check in accordance with section 8.4.

10.3.3 Except as noted in section 10.3.3.3, calibrate all differential pressure-measuring devices to be used in the probe calibrations, using the following procedures. At a minimum, calibrate these devices on each day that probe calibrations are performed. 10.3.3.1 Procedure. Before each wind tunnel use, all differential pressure measuring devices shall be calibrated against the reference device specified in section 6.4.3 using a common pressure source. Perform the calibration at three reference pressures representing 30, 60, and 90 percent of the full-scale range of the pressure-measuring device being calibrated. For an inclined vertical manometer, perform separate calibrations on the inclined and vertical portions of the measurement scale, considering each portion of the scale to be a separate full-scale range. [For example, for a manometer with a 0-to 2.5-cm H<sub>2</sub>O (0-to 1 in. H<sub>2</sub>O) inclined scale and a 2.5-to 12.7-cm H<sub>2</sub>O (1-to 5-in. H<sub>2</sub>O) vertical scale, calibrate the inclined portion at 7.6, 15.2, and 22.9 mm H<sub>2</sub>O (0.3, 0.6, and 0.9 in. H<sub>2</sub>O), and calibrate the vertical portion at 3.8, 7.6, and 11.4 cm H<sub>2</sub>O (1.5, 3.0, and 4.5 in. H<sub>2</sub>O). Alternatively, for the vertical portion of the scale, use three evenly spaced reference pressures, one of which is equal to or higher than the highest differential pressure expected in field applications. 10.3.3.2 Acceptance criteria. At each pressure setting, the two pressure readings made using the reference device and the pressure-measuring device being calibrated shall agree to within #2 percent of full scale of the device being calibrated or 0.5 mm H<sub>2</sub>O  $(0.02 \text{ in. } H_2O)$ , whichever is less restrictive. For an inclined-vertical manometer, these

26530

requirements shall be met separately using the respective full-scale upper limits of the inclined and vertical portions of the scale. Differential pressure-measuring devices not meeting the #2 percent of full scale or 0.5 mm H<sub>2</sub>O (0.02 in. H<sub>2</sub>O) calibration requirement shall not be used. 10.3.3.3 Exceptions. Any precision manometer that meets the specifications for a reference device in section 6.4.3 and that is not used for field testing does not require calibration, but must be leveled and zeroed before each wind tunnel use. Any pressure device used exclusively for yaw nulling does not require calibration, but shall be checked for responsiveness to rotation of the probe prior to each wind tunnel use.

10.3.4 Calibrate digital inclinometers on each day of wind tunnel or field testing (prior to beginning testing) using the following procedures. Calibrate the inclinometer according to the manufacturer's calibration procedures. In addition, use a triangular block (illustrated in Figure 2G–9) with a known angle, ", independently determined using a protractor or equivalent device, between two adjacent sides to verify the inclinometer readings. (Note: If other anglemeasuring devices meeting the provisions of section 6.2.3 are used in place of a digital inclinometer, comparable calibration procedures shall be performed on such devices.) Secure the triangular block in a fixed position. Place the inclinometer on one side of the block (side A) to measure the angle of inclination  $(R_1)$ . Repeat this measurement on the adjacent side of the block (side B) using the inclinometer to obtain a second angle reading  $(R_2)$ . The difference of the sum of the two readings from 180° (i.e.,  $180R_1R_2$ ) shall be within #2 of the known angle,

10.4 Placement of Reference Scribe Line. Prior to the first calibration of a probe, a line shall be permanently inscribed on the main probe sheath to serve as a reference mark for determining yaw angles. Annex C in section 18 of this method gives a guideline for placement of the reference scribe line. 10.4.1 This reference scribe line shall meet the specifications in sections 6.1.5.1 and 6.1.5.3 of this method. To verify that the alignment specification in section 6.1.5.3 is met, secure the probe in a horizontal position and measure the rotational angle of each scribe line and scribe line segment using an angle-measuring device that meets the specifications in section 6.2.1 or 6.2.3. For any scribe line that is longer than 30.5 cm (12 in.), check the line's rotational position at 30.5-cm (12-in.) intervals. For each line segment that is 12 in. or less in length, check the rotational position at the two endpoints of the segment. To meet the alignment specification in section 6.1.5.3, the minimum and maximum of all of the rotational angles that are measured along the full length of main probe must not differ by more than 2°. (Note: A short reference scribe line segment [e.g., 15.2 cm (6 in.) or less in length] meeting the alignment specifications in section 6.1.5.3 is fully acceptable under this method. See section 18.1.1.1 of Annex A for an example of a probe marking procedure, suitable for use with a short reference scribe line.)

10.4.2 The scribe line should be placed on the probe first and then its offset from the yaw-null position established (as specified in section 10.5). The rotational position of the reference scribe line relative to the yaw-null position of the probe, as determined by the yaw angle calibration procedure in section 10.5, is the reference scribe line rotational offset,  $R_{\rm SLO}$ . The reference scribe line rotational offset shall be recorded and retained as part of the probe's calibration record.

10.4.3 Scribe line for automated probes. A scribe line may not be necessary for an automated probe system if a reference rotational position of the probe is built into the probe system design. For such systems, a "flat" (or comparable, clearly identifiable physical characteristic) should be provided on the probe casing or flange plate to ensure that the reference position of the probe assembly remains in a vertical or horizontal position. The rotational offset of the flat (or comparable, clearly identifiable physical characteristic) needed to orient the reference position of the probe assembly shall be recorded and maintained as part of the automated probe system's specifications.

10.5 Yaw Angle Calibration Procedure. For each probe used to measure yaw angles with this method, a calibration procedure shall be performed in a wind tunnel meeting the specifications in section 10.1 to determine the rotational position of the reference scribe line relative to the probe's yaw-null position. This procedure shall be performed on the main probe with all devices that will be attached to the main probe in the field [such as thermocouples, resistance temperature detectors (RTDs), or sampling nozzles] that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration. At a minimum, this procedure shall include the following steps.

10.5.1 Align and lock the anglemeasuring device on the reference scribe line. If a marking procedure (such as described in section 18.1.1.1) is used, align the angle-measuring device on a mark within  $\pm 1^{\circ}$  of the rotational position of the reference scribe line. Lock the angle-measuring device onto the probe sheath at this position.

10.5.2 Zero the pressure-measuring device used for yaw nulling.

10.5.3 Insert the probe assembly into the wind tunnel through the entry port, positioning the probe's impact port at the calibration location. Check the responsiveness of the pressure-measurement device to probe rotation, taking corrective action if the response is unacceptable.

10.5.4 Ensure that the probe is in a horizontal position, using a carpenter's level.

10.5.5 Rotate the probe either clockwise or counterclockwise until a yaw null [zero  $\Delta P$ for a Type S probe or zero (P<sub>2</sub>-P<sub>3</sub>) for a 3– D probe] is obtained. If using a Type S probe with an attached thermocouple, the direction of the probe rotation shall be such that the thermocouple is located downstream of the probe pressure ports at the yaw-null position.

10.5.6 Use the reading displayed by the angle-measuring device at the yaw-null position to determine the magnitude of the

reference scribe line rotational offset, R<sub>SLO</sub>, as defined in section 3.15. Annex D in section 18 of this method gives a recommended procedure for determining the magnitude of R<sub>SLO</sub> with a digital inclinometer and a second procedure for determining the magnitude of R<sub>SLO</sub> with a protractor wheel and pointer device. Table 2G-6 gives an example data form and Table 2G-7 is a look-up table with the recommended procedure. Procedures other than those recommended in Annex D in section 18 may be used, if they can determine  $R_{\rm SLO}$  to within 1° and are explained in detail in the field test report. The algebraic sign of R<sub>SLO</sub> will either be positive if the rotational position of the reference scribe line (as viewed from the "tail" end of the probe) is clockwise, or negative, if counterclockwise with respect to the probe's yaw-null position. (This is illustrated in Figure 2G-10.)

10.5.7 The steps in sections 10.5.3 through 10.5.6 shall be performed twice at each of the velocities at which the probe will be calibrated (in accordance with section 10.6). Record the values of  $R_{\rm SLO}$ .

10.5.8 The average of all of the RSLO values shall be documented as the reference scribe line rotational offset for the probe.

10.5.9 Use of reference scribe line offset. The reference scribe line rotational offset shall be used to determine the yaw angle of flow in accordance with section 8.9.4.

10.6 Velocity Calibration Procedure. When a 3-D probe is used under this method, follow the provisions for the calibration of 3-D probes in section 10.6 of Method 2F to obtain the necessary velocity calibration coefficients (F2 as derived using Equation 2F-2 in Method 2F) corresponding to a pitch angle position of 0°. The following procedure applies to Type S probes. This procedure shall be performed on the main probe and all devices that will be attached to the main probe in the field (e.g., thermocouples, RTDs, sampling nozzles) that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration. (Note: If a sampling nozzle is part of the assembly, two additional requirements must be satisfied before proceeding. The distance between the nozzle and the pitot tube shall meet the minimum spacing requirement prescribed in Method 2, and a wind tunnel demonstration shall be performed that shows the probe's ability to yaw null is not impaired when the nozzle is drawing sample.) To obtain velocity calibration coefficient(s) for the tested probe, proceed as follows.

10.6.1 Calibration velocities. The tester may calibrate the probe at two nominal wind tunnel velocity settings of 18.3 m/sec and 27.4 m/sec (60 ft/sec and 90 ft/sec) and average the results of these calibrations, as described in sections 10.6.12 through 10.6.14, in order to generate the calibration coefficient,  $C_p$ . If this option is selected, this calibration coefficient may be used for all field applications where the velocities are 9.1 m/sec (30 ft/sec) or greater. Alternatively, the tester may customize the probe calibration for a particular field test application (or for a series of applications), based on the expected average velocity(ies) at the test site(s). If this option is selected, generate the calibration coefficients by calibrating the probe at two nominal wind tunnel velocity settings, one of which is less than or equal to the date of the other greater than or equal to the expected average velocity(ies) for the field application(s), and average the results as described in sections 10.6.12 through 10.6.14. Whichever calibration option is selected, the probe calibration coefficient(s) obtained at the two nominal calibration velocities shall meet the conditions specified in sections 10.6.12 through 10.6.14.

10.6.2 Connect the tested probe and calibration pitot tube to their respective pressure-measuring devices. Zero the pressure-measuring devices. Inspect and leak-check all pitot lines; repair or replace them, if necessary. Turn on the fan, and allow the wind tunnel air flow to stabilize at the first of the selected nominal velocity settings.

10.6.3 Position the calibration pitot tube at its measurement location (determined as outlined in section 6.11.4.3), and align the tube so that its tip is pointed directly into the flow. Ensure that the entry port surrounding the tube is properly sealed. The calibration pitot tube may either remain in the wind tunnel throughout the calibration, or be removed from the wind tunnel while measurements are taken with the probe being calibrated.

10.6.4 Check the zero setting of each pressure-measuring device.

10.6.5 Insert the tested probe into the wind tunnel and align it so that the designated pressure port (e.g., either the A-side or B-side of a Type S probe) is pointed directly into the flow and is positioned within the wind tunnel calibration location (as defined in section 3.21). Secure the probe

at the  $0^{\circ}$  pitch angle position. Ensure that the entry port surrounding the probe is properly sealed.

10.6.6 Read the differential pressure from the calibration pitot tube ( $\Delta$ Pstd), and record its value. Read the barometric pressure to within ±2.5 mm Hg (±0.1 in. Hg) and the temperature in the wind tunnel to within 0.6°C (1°F). Record these values on a data form similar to Table 2G–8.

10.6.7 After the tested probe's differential pressure gauges have had sufficient time to stabilize, yaw null the probe (and then rotate it back 90° for Type S probes), then obtain the differential pressure reading ( $\Delta P$ ). Record the yaw angle and differential pressure readings.

10.6.8 Take paired differential pressure measurements with the calibration pitot tube and tested probe (according to sections 10.6.6 and 10.6.7). The paired measurements in each replicate can be made either simultaneously (i.e., with both probes in the wind tunnel) or by alternating the measurements of the two probes (i.e., with only one probe at a time in the wind tunnel).

10.6.9 Repeat the steps in sections 10.6.6 through 10.6.8 at the same nominal velocity setting until three pairs of  $\Delta P$  readings have been obtained from the calibration pitot tube and the tested probe.

10.6.10 Repeat the steps in sections 10.6.6 through 10.6.9 above for the A-side and B-side of the Type S pitot tube. For a probe assembly constructed such that its pitot tube is always used in the same orientation, only one side of the pitot tube need be calibrated (the side that will face the flow). However, the pitot tube must still meet the alignment and dimension specifications in section 6.1.1 and must have an average deviation ( $\sigma$ ) value of 0.01 or less as provided in section 10.6.12.4.

10.6.11 Repeat the calibration procedures in sections 10.6.6 through 10.6.10 at the second selected nominal wind tunnel velocity setting.

10.6.12 Perform the following calculations separately on the A-side and B-side values.

10.6.12.1 Calculate a  $C_{\rho}$  value for each of the three replicates performed at the lower velocity setting where the calibrations were performed using Equation 2–2 in section 4.1.4 of Method 2.

10.6.12.2 Calculate the arithmetic average,  $C_{p(avg-low)}$ , of the three  $C_p$  values. 10.6.12.3 Calculate the deviation of each

of the three individual values of  $C_p$  from the A-side average  $C_{p(avg-low)}$  value using Equation 2–3 in Method 2.

10.6.12.4 Calculate the average deviation ( $\sigma$ ) of the three individual  $C_p$  values from  $C_{p(avg-low)}$  using Equation 2–4 in Method 2. Use the Type S pitot tube only if the values of  $\sigma$  (side A) and  $\sigma$  (side B) are less than or equal to 0.01. If both A-side and B-side calibration coefficients are calculated, the absolute value of the difference between  $C_{p(avg-low)}$  (side A) and  $C_{p(avg-low)}$  (side B) must not exceed 0.01.

10.6.13 Repeat the calculations in section 10.6.12 using the data obtained at the higher velocity setting to derive the arithmetic  $C_{\rm p}$  values at the higher velocity setting,  $C_{\rm p(avg-high)}$ , and to determine whether the conditions in 10.6.12.4 are met by both the A-side and B-side calibrations at this velocity setting.

10.6.14 Use equation 2G-1 to calculate the percent difference of the averaged  $C_p$  values at the two calibration velocities.

$$\% \text{Difference} = \frac{C_{p_{(avg-low)}} - C_{p_{(avg-high})}}{C_{p_{(avg-low)}}} \times 100\% \text{ Eq. 2G-1}$$

The percent difference between the averaged  $C_p$  values shall not exceed  $\pm 3$  percent. If the specification is met, average the A-side values of  $C_{p(avg-low)}$  and  $C_{p(avg-high)}$  to produce a single A-side calibration coefficient,  $C_p$ . Repeat for the B-side values if calibrations were performed on that side of the pitot. If the specification is not met, make necessary adjustments in the selected velocity settings and repeat the calibration procedure until acceptable results are obtained.

10.6.15 If the two nominal velocities used in the calibration were 18.3 and 27.4 m/sec (60 and 90 ft/sec), the average  $C_p$  from section 10.6.14 is applicable to all velocities 9.1 m/ sec (30 ft/sec) or greater. If two other nominal velocities were used in the calibration, the resulting average  $C_p$  value shall be applicable only in situations where the velocity calculated using the calibration coefficient is neither less than the lower nominal velocity nor greater than the higher nominal velocity.

10.7 Recalibration. Recalibrate the probe using the procedures in section 10 either within 12 months of its first field use after its most recent calibration or after 10 field tests (as defined in section 3.3), whichever occurs later. In addition, whenever there is visible damage to the probe head, the probe shall be recalibrated before it is used again.

10.8 Calibration of pressure-measuring devices used in the field. Before its initial use in a field test, calibrate each pressure measuring device (except those used exclusively for yaw nulling) using the threepoint calibration procedure described in section 10.3.3. The device shall be recalibrated according to the procedure in section 10.3.3 no later than 90 days after its first field use following its most recent calibration. At the discretion of the tester, more frequent calibrations (e.g., after a field test) may be performed. No adjustments, other than adjustments to the zero setting. shall be made to the device between calibrations.

10.8.1 Post-test calibration check. A single-point calibration check shall be performed on each pressure-measuring device after completion of each field test. At the discretion of the tester, more frequent single-point calibration checks (e.g., after one or more field test runs) may be performed. It is recommended that the post-test check be

performed before leaving the field test site. The check shall be performed at a pressure between 50 and 90 percent of full scale by taking a common pressure reading with the tested probe and a reference pressuremeasuring device (as described in section 6.4.4) or by challenging the tested device with a reference pressure source (as described in section 6.4.4) or by performing an equivalent check using a reference device approved by the Administrator.

10.8.2 Acceptance criterion. At the selected pressure setting, the pressure readings made using the reference device and the tested device shall agree to within  $\pm 3$  percent of full scale of the tested device or 0.8 mm H<sub>2</sub>O (0.03 in. H<sub>2</sub>O), whichever is less restrictive. If this specification is met, the test data collected during the field test are valid. If the specification is not met, all test data collected since the last successful calibration or calibration check are invalid and shall be repeated using a pressure-measuring device with a current, valid calibration. Any device that fails the calibration check shall not be used in a field test until a successful

26532

recalibration is performed according to the procedures in section 10.3.3.

10.9 Temperature Gauges. Same as Method 2, section 4.3. The alternative thermocouple calibration procedures outlined in Emission Measurement Center (EMC) Approved Alternative Method (ALT-011) "Alternative Method 2 Thermocouple Calibration Procedure" may be performed. Temperature gauges shall be calibrated no more than 30 days prior to the start of a field test or series of field tests and recalibrated no more than 30 days after completion of a field test or series of field tests.

10.10 Barometer. Same as Method 2. section 4.4. The barometer shall be calibrated no more than 30 days prior to the start of a field test or series of field tests.

## 11.0 Analytical Procedure

Sample collection and analysis are concurrent for this method (see section 8.0).

## 12.0 Data Analysis and Calculations

These calculations use the measured yaw angle and the differential pressure and temperature measurements at individual traverse points to derive the near-axial flue gas velocity (a(ii)) at each of those points. The near-axial velocity values at all traverse points that comprise a full stack or duct traverse are then averaged to obtain the average near-axial stack or duct gas velocity a(avg).

- 12.1 Nomenclature
- A = Cross-sectional area of stack or duct at the test port location,  $m_2$  (ft<sub>2</sub>).
- $B_{\rm ws}$ = Water vapor in the gas stream (from Method 4 or alternative), proportion by volume.
- C<sub>p</sub> = Pitot tube calibration coefficient, dimensionless.
- $F_{2(i)} = 3$ -D probe velocity coefficient at 0 pitch, applicable at traverse point i.
- K<sub>p</sub> = Pitot tube constant,

$$34.97 \frac{\text{m}}{\text{sec}} \left[ \frac{(\text{g/g} - \text{mole})(\text{mm Hg})}{(^{\circ} \text{K})(\text{mm H}_2 \text{O})} \right]^{1/2}$$

for the metric system, and

$$85.49 \frac{\text{ft}}{\text{sec}} \left[ \frac{(\text{lb/lb-mole})(\text{in. Hg})}{(^{\circ}\text{R})(\text{in. H}_2\text{O})} \right]^{1/2}$$

for the English system.

- $M_d$  = Molecular weight of stack or duct gas, dry basis (see section 8.13), g/g-mole (lb/ lb-mole).
- $M_s$  = Molecular weight of stack or duct gas, wet basis, g/g-mole (lb/lb-mole).

$$M_s = M_d (1 - B_{ws}) + 18.0B_{ws}$$
 Eq. 2G-2

- P<sub>bar</sub> = Barometric pressure at velocity measurement site, mm Hg (in. Hg).
- $P_g$  = Stack or duct static pressure, mm H<sub>2</sub>O  $(in, H_2O)$ .
- $P_s$  = Absolute stack or duct pressure, mm Hg (in. Hg),

$$P_{s} = P_{bar} + \frac{P_{g}}{13.6}$$
 Eq. 2G-3

- P<sub>std</sub> = Standard absolute pressure, 760 mm Hg (29.92 in. Hg).
- $13.6 = \text{Conversion from mm } H_2O$  (in.  $H_2O$ ) to mm Hg (in. Hg).
- Q<sub>sd</sub> = Average dry-basis volumetric stack or duct gas flow rate corrected to standard conditions, dscm/hr (dscf/hr).
- = Average wet-basis volumetric stack or Qsw duct gas flow rate corrected to standard conditions, wscm/hr (wscf/hr).
- $ts_{(i)} = Stack \text{ or duct temperature, } ^{\circ}C (^{\circ}F), at$ traverse point i.
- $T_{s(i)}$  = Absolute stack or duct temperature, °K (°R), at traverse point i.

$$\mathbf{v}_{a(i)} = \mathbf{K}_{p} \mathbf{C}_{p} \sqrt{\frac{(\Delta \mathbf{P})_{i} \mathbf{T}_{s(i)}}{\mathbf{P}_{s} \mathbf{M}_{s}}} \left( \cos \theta_{y(i)} \right) \qquad \text{Eq. 2G-6}$$

$$T_{s(i)} = 273 + t_{s(i)}$$
 Eq. 2G-4

for the metric system, and

$$T_{s(i)} = 460 + t_{s(i)}$$
 Eq. 2G-5

for the English system.

\_

- T<sub>s(avg)</sub>=Average absolute stack or duct gas
- temperature across all traverse points. T<sub>std</sub>=Standard absolute temperature, 293°K (528°R).
- v<sub>a(i)</sub>=Measured stack or duct gas impact velocity, m/sec (ft/sec), at traverse point i.
- v<sub>a(avg)</sub>=Average near-axial stack or duct gas velocity, m/sec (ft/sec) across all traverse points.
- $\Delta P_i$ =Velocity head (differential pressure) of stack or duct gas, mm H<sub>2</sub>O (in. H<sub>2</sub>O), applicable at traverse point i.
- $(P_1-P_2)$ =Velocity head (differential pressure) of stack or duct gas measured by a 3-D probe, mm H<sub>2</sub>O (in. H<sub>2</sub>O), applicable at traverse point i.
- 3,600=Conversion factor, sec/hr.
- 18.0=Molecular weight of water, g/g-mole (lb/lb-mole).
- $\theta_{y(i)}$ =Yaw angle of the flow velocity vector, at traverse point i.

n=Number of traverse points.

12.2 Traverse Point Velocity Calculations. Perform the following calculations from the measurements obtained at each traverse point.

12.2.1 Selection of calibration coefficient. Select the calibration coefficient as described in section 10.6.1.

12.2.2 Near-axial traverse point velocity. When using a Type S probe, use the following equation to calculate the traverse point near-axial velocity  $(v_{a(i)})$  from the differential pressure ( $\Delta \tilde{P}_i$ ), yaw angle ( $\theta_{y(i)}$ ), absolute stack or duct standard temperature  $(T_{s(i)})$  measured at traverse point i, the absolute stack or duct pressure (Ps), and molecular weight (M<sub>s</sub>).

Use the following equation when using a 3-D probe.

$$v_{a(i)} = K_p F_2 \sqrt{\frac{(P_1 - P_2)_i T_{s(i)}}{P_s M_s}} (\cos \theta_{y(i)})$$
 Eq. 2G-7

calculating the applicable traverse point

 $v_{a(avg)} = \frac{\sum_{i=1}^{n} v_{a(i)}}{n}$ 

12.3 Average Near-Axial Velocity in

Stack or Duct. Use the reported traverse point

near-axial velocity in the following equation.

Eq. 2G-8

value.

12.2.3 Handling multiple measurements approach, all of the individual measurements at a traverse point. For pressure or recorded at a traverse point must be used in temperature devices that take multiple measurements at a traverse point, the multiple measurements (or where applicable, their square roots) may first be averaged and the resulting average values used in the equations above. Alternatively, the individual measurements may be used in the equations above and the resulting calculated values may then be averaged to obtain a single traverse point value. With either

12.4 Acceptability of Results. The acceptability provisions in section 12.4 of Method 2F apply to 3-D probes used under Method 2G. The following provisions apply to Type S probes. For Type S probes, the test results are acceptable and the calculated value of  $v_{a(avg)}$  may be reported as the average near-axial velocity for the test run if the conditions in either section 12.4.1 or 12.4.2 are met.

12.4.1 The average calibration coefficient C<sub>p</sub> used in Equation 2G-6 was generated at

nominal velocities of 18.3 and 27.4 m/sec (60 and 90 ft/sec) and the value of  $v_{a(avg)}$  calculated using Equation 2G–8 is greater than or equal to 9.1 m/sec (30 ft/sec).

12.4.2 The average calibration coefficient  $C_p$  used in Equation 2G–6 was generated at nominal velocities other than 18.3 or 27.4 m/ sec (60 or 90 ft/sec) and the value of  $v_{a(avg)}$ 

calculated using Equation 2G-8 is greater than or equal to the lower nominal velocity and less than or equal to the higher nominal velocity used to derive the average  $C_p$ .

12.4.3 If the conditions in neither section 12.4.1 nor section 12.4.2 are met, the test results obtained from Equation 2G–8 are not acceptable, and the steps in sections 12.2 and

12.3 must be repeated using an average calibration coefficient  $C_{\rm p}$  that satisfies the conditions in section 12.4.1 or 12.4.2.

12.5 Average Gas Volumetric Flow Rate in Stack or Duct (Wet Basis). Use the following equation to compute the average volumetric flow rate on a wet basis.

$$Q_{sw} = 3,600 \left( v_{a(avg)} \right) (A) \left( \frac{T_{std}}{T_{s(avg)}} \right) \left( \frac{P_s}{P_{std}} \right) \qquad Eq. \ 2G-9$$

12.6 Average Gas Volumetric Flow Rate following equation Stack or Duct (Dry Basis). Use the volumetric flow

following equation to compute the average volumetric flow rate on a dry basis.

$$Q_{sd} = 3,600(1 - B_{ws})(v_{a(avg)})(A)\left(\frac{T_{std}}{T_{s(avg)}}\right)\left(\frac{P_s}{P_{std}}\right) \qquad Eq. \ 2G-10$$

- 13.0 Method Performance. [Reserved]
- 14.0 Pollution Prevention. [Reserved]
- 15.0 Waste Management. [Reserved]
- 16.0 Reporting.
- 16.1 Field Test Reports. Field test reports shall be submitted to the Agency according to applicable regulatory requirements. Field test reports should, at a minimum, include the following elements.
- 16.1.1 Description of the source. This should include the name and location of the test site, descriptions of the process tested, a description of the combustion source, an accurate diagram of stack or duct cross-sectional area at the test site showing the dimensions of the stack or duct, the location of the test ports, and traverse point locations and identification numbers or codes. It should also include a description and diagram of the stack or duct layout, showing the distance of the test location from the nearest upstream and downstream disturbances and all structural elements (including breachings, baffles, fans, straighteners, etc.) affecting the flow pattern. If the source and test location descriptions have been previously submitted to the Agency in a document (e.g., a monitoring plan or test plan), referencing the document in lieu of including this information in the field test report is acceptable.
- 16.1.2 Field test procedures. These should include a description of test equipment and test procedures. Testing conventions, such as traverse point numbering and measurement sequence (e.g., sampling from center to wall, or wall to center), should be clearly stated. Test port identification and directional reference for each test port should be included on the appropriate field test data sheets.
- 16.1.3 Field test data.

- 16.1.3.1 Summary of results. This summary should include the dates and times of testing, and the average near-axial gas velocity and the average flue gas volumetric flow results for each run and tested condition.
- 16.1.3.2 Test data. The following values for each traverse point should be recorded and reported:
- (a) Differential pressure at traverse point i  $(\Delta P_i)$
- (b) Stack or duct temperature at traverse point i (t<sub>s(i)</sub>)
- (c) Absolute stack or duct temperature at traverse point i  $(T_{s(i)})$
- (d) Yaw angle at traverse point i  $(\theta_{v(i)})$
- (e) Stack gas near-axial velocity at traverse point i  $(v_{a(i)})$

16.1.3.3 The following values should be reported once per run:

- (a) Water vapor in the gas stream (from Method 4 or alternative), proportion by volume (B<sub>ws</sub>), measured at the frequency specified in the applicable regulation
- (b) Molecular weight of stack or duct gas, dry basis  $(M_d)$
- (c) Molecular weight of stack or duct gas, wet basis (M<sub>s</sub>)
- (d) Stack or duct static pressure (Pg)
- (e) Absolute stack or duct pressure (Ps)
- (f) Carbon dioxide concentration in the flue gas, dry basis ( $%_d CO_2$ )
- (g) Oxygen concentration in the flue gas, dry basis ( $\%_d O_2$ )
- (h) Average near-axial stack or duct gas velocity  $(v_{a(avg)})$  across all traverse points
- (i) Gas volumetric flow rate corrected to standard conditions, dry or wet basis as required by the applicable regulation ( $Q_{sd}$  or  $Q_{sw}$ )

16.1.3.4 The following should be reported once per complete set of test runs:

- (a) Cross-sectional area of stack or duct at the test location (A)
- (b) Pitot tube calibration coefficient (C<sub>p</sub>)
- (c) Measurement system response time (sec)(d) Barometric pressure at measurement site
- (P<sub>bar</sub>)
- 16.1.4 Calibration data. The field test report should include calibration data for all

probes and test equipment used in the field test. At a minimum, the probe calibration data reported to the Agency should include the following:

- (a) Date of calibration
- (b) Probe type
- (c) Probe identification number(s) or code(s)
- (d) Probe inspection sheets
- (e) Pressure measurements and calculations used to obtain calibration coefficients in accordance with section 10.6 of this method
- (f) Description and diagram of wind tunnel used for the calibration, including dimensions of cross-sectional area and position and size of the test section
- (g) Documentation of wind tunnel qualification tests performed in accordance with section 10.1 of this method

16.1.5 Quality assurance. Specific quality assurance and quality control procedures used during the test should be described.

### 18.0 Annexes

Annex A, C, and D describe recommended procedures for meeting certain provisions in sections 8.3, 10.4, and 10.5 of this method. Annex B describes procedures to be followed when using the protractor wheel and pointer assembly to measure yaw angles, as provided under section 8.9.1.

18.1 Annex A—Rotational Position Check. The following are recommended procedures that may be used to satisfy the rotational position check requirements of section 8.3 of this method and to determine the angle-measuring device rotational offset ( $R_{ADO}$ ).

18.1.1 Rotational position check with probe outside stack. Where physical constraints at the sampling location allow full assembly of the probe outside the stack and insertion into the test port, the following procedures should be performed before the start of testing. Two angle-measuring devices that meet the specifications in section 6.2.1 or 6.2.3 are required for the rotational position check. An angle measuring device whose position can be independently adjusted (e.g., by means of a set screw) after being locked into position on the probe sheath shall not be used for this check unless the independent adjustment is set so that the device performs exactly like a device without the capability for independent adjustment. That is, when aligned on the probe such a device must give the same reading as a device that does not have the capability of being independently adjusted. With the fully assembled probe (including probe shaft extensions, if any) secured in a horizontal position, affix one yaw angle-measuring device to the probe sheath and lock it into position on the reference scribe line specified in section 6.1.5.1. Position the second anglemeasuring device using the procedure in section 18.1.1.1 or 18.1.1.2.

18.1.1.1 Marking procedure. The procedures in this section should be performed at each location on the fully assembled probe where the yaw angle-

measuring device will be mounted during the velocity traverse. Place the second yaw anglemeasuring device on the main probe sheath (or extension) at the position where a yaw angle will be measured during the velocity traverse. Adjust the position of the second angle-measuring device until it indicates the same angle  $(\pm 1^{\circ})$  as the reference device, and affix the second device to the probe sheath (or extension). Record the angles indicated by the two angle-measuring devices on a form similar to table 2G–2. In this position, the second angle-measuring device is considered to be properly positioned for yaw angle measurement. Make a mark, no wider than 1.6 mm (1/16 in.), on the probe sheath (or extension), such that the yaw anglemeasuring device can be re-affixed at this same properly aligned position during the velocity traverse.

18.1.1.2 Procedure for probe extensions with scribe lines. If, during a velocity traverse the angle-measuring device will be affixed to a probe extension having a scribe line as specified in section 6.1.5.2, the following procedure may be used to align the extension's scribe line with the reference scribe line instead of marking the extension as described in section 18.1.1.1. Attach the probe extension to the main probe. Align and lock the second angle-measuring device on the probe extension's scribe line. Then, rotate the extension until both measuring devices indicate the same angle  $(\pm 1^\circ)$ . Lock the extension at this rotational position. Record the angles indicated by the two anglemeasuring devices on a form similar to table 2G-2. An angle-measuring device may be aligned at any position on this scribe line during the velocity traverse, if the scribe line meets the alignment specification in section 6.1.5.3.

18.1.1.3 Post-test rotational position check. If the fully assembled probe includes one or more extensions, the following check should be performed immediately after the completion of a velocity traverse. At the discretion of the tester, additional checks may be conducted after completion of testing at any sample port. Without altering the alignment of any of the components of the probe assembly used in the velocity traverse, secure the fully assembled probe in a horizontal position. Affix an angle-measuring device at the reference scribe line specified in section 6.1.5.1. Use the other anglemeasuring device to check the angle at each location where the device was checked prior to testing. Record the readings from the two angle-measuring devices.

18.1.2 Rotational position check with probe in stack. This section applies only to probes that, due to physical constraints, cannot be inserted into the test port as fully assembled with all necessary extensions needed to reach the inner-most traverse point(s).

18.1.2.1 Perform the out-of-stack procedure in section 18.1.1 on the main probe and any attached extensions that will be initially inserted into the test port.

18.1.2.2 Use the following procedures to perform additional rotational position check(s) with the probe in the stack, each time a probe extension is added. Two anglemeasuring devices are required. The first of

these is the device that was used to measure yaw angles at the preceding traverse point, left in its properly aligned measurement position. The second angle-measuring device is positioned on the added probe extension. Use the applicable procedures in section 18.1.1.1 or 18.1.1.2 to align, adjust, lock, and mark (if necessary) the position of the second angle-measuring device to within  $\pm 1^{\circ}$  of the first device. Record the readings of the two devices on a form similar to Table 2G–2.

18.1.2.3 The procedure in section 18.1.2.2 should be performed at the first port where measurements are taken. The procedure should be repeated each time a probe extension is re-attached at a subsequent port, unless the probe extensions are designed to be locked into a mechanically fixed rotational position (e.g., through use of interlocking grooves), which can be reproduced from port to port as specified in section 8.3.5.2.

18.2 Annex B—Angle Measurement Protocol for Protractor Wheel and Pointer Device. The following procedure shall be used when a protractor wheel and pointer assembly, such as the one described in section 6.2.2 and illustrated in Figure 2G-5 is used to measure the yaw angle of flow. With each move to a new traverse point, unlock, re-align, and re-lock the probe, anglepointer collar, and protractor wheel to each other. At each such move, particular attention is required to ensure that the scribe line on the angle pointer collar is either aligned with the reference scribe line on the main probe sheath or is at the rotational offset position established under section 8.3.1. The procedure consists of the following steps:

18.2.1 Affix a protractor wheel to the entry port for the test probe in the stack or duct.

18.2.2 Orient the protractor wheel so that the 0° mark corresponds to the longitudinal axis of the stack or duct. For stacks, vertical ducts, or ports on the side of horizontal ducts, use a digital inclinometer meeting the specifications in section 6.2.1 to locate the 0° orientation. For ports on the top or bottom of horizontal ducts, identify the longitudinal axis at each test port and permanently mark the duct to indicate the 0° orientation. Once the protractor wheel is properly aligned, lock it into position on the test port.

18.2.3 Move the pointer assembly along the probe sheath to the position needed to take measurements at the first traverse point. Align the scribe line on the pointer collar with the reference scribe line or at the rotational offset position established under section 8.3.1. Maintaining this rotational alignment, lock the pointer device onto the probe sheath. Insert the probe into the entry port to the depth needed to take measurements at the first traverse point.

18.2.4 Perform the yaw angle determination as specified in sections 8.9.3 and 8.9.4 and record the angle as shown by the pointer on the protractor wheel. Then, take velocity pressure and temperature measurements in accordance with the procedure in section 8.9.5. Perform the alignment check described in section 8.9.6.

18.2.5 After taking velocity pressure measurements at that traverse point, unlock

the probe from the collar and slide the probe through the collar to the depth needed to reach the next traverse point.

18.2.6 Align the scribe line on the pointer collar with the reference scribe line on the main probe or at the rotational offset position established under section 8.3.1. Lock the collar onto the probe.

18.2.7 Repeat the steps in sections 18.2.4 through 18.2.6 at the remaining traverse points accessed from the current stack or duct entry port.

18.2.8 Åfter completing the measurement at the last traverse point accessed from a port, verify that the orientation of the protractor wheel on the test port has not changed over the course of the traverse at that port. For stacks, vertical ducts, or ports on the side of horizontal ducts, use a digital inclinometer meeting the specifications in section 6.2.1 to check the rotational position of the 0° mark on the protractor wheel. For ports on the top or bottom of horizontal ducts, observe the alignment of the angle wheel 0° mark relative to the permanent 0° mark on the duct at that test port. If these observed comparisons exceed  $\pm 2^{\circ}$  of  $0^{\circ}$ , all angle and pressure measurements taken at that port since the protractor wheel was last locked into position on the port shall be repeated.

18.2.9 Move to the next stack or duct entry port and repeat the steps in sections 18.2.1 through 18.2.8.

18.3 Annex C—Guideline for Reference Scribe Line Placement. Use of the following guideline is recommended to satisfy the requirements of section 10.4 of this method. The rotational position of the reference scribe line should be either 90° or 180° from the probe's impact pressure port. For Type-S probes, place separate scribe lines, on opposite sides of the probe sheath, if both the A and B sides of the pitot tube are to be used for yaw angle measurements.

18.4 Annex D—Determination of Reference Scribe Line Rotational Offset. The following procedures are recommended for determining the magnitude and sign of a probe's reference scribe line rotational offset, R<sub>SLO</sub>. Separate procedures are provided for two types of angle-measuring devices: digital inclinometers and protractor wheel and pointer assemblies.

18.4.1 Perform the following procedures on the main probe with all devices that will be attached to the main probe in the field [such as thermocouples, resistance temperature detectors (RTDs), or sampling nozzles] that may affect the flow around the probe head. Probe shaft extensions that do not affect flow around the probe head need not be attached during calibration.

18.4.2 The procedures below assume that the wind tunnel duct used for probe calibration is horizontal and that the flow in the calibration wind tunnel is axial as determined by the axial flow verification check described in section 10.1.2. Anglemeasuring devices are assumed to display angles in alternating 0° to 90° and 90° to 0° intervals. If angle-measuring devices with other readout conventions are used or if other calibration wind tunnel duct configurations are used, make the appropriate calculational corrections. For Type-S probes, calibrate the A-side and B-sides separately, using the appropriate scribe line (see section 18.3, above), if both the A and B sides of the pitot tube are to be used for yaw angle determinations.

18.4.2.1 Position the angle-measuring device in accordance with one of the following procedures.

18.4.2.1.1 If using a digital inclinometer, affix the calibrated digital inclinometer to the probe. If the digital inclinometer can be independently adjusted after being locked into position on the probe sheath (e.g., by means of a set screw), the independent adjustment must be set so that the device performs exactly like a device without the capability for independent adjustment. That is, when aligned on the probe the device must give the same readings as a device that does not have the capability of being independently adjusted. Either align it directly on the reference scribe line or on a mark aligned with the scribe line determined according to the procedures in section 18.1.1.1. Maintaining this rotational alignment, lock the digital inclinometer onto the probe sheath.

18.4.2.1.2 If using a protractor wheel and pointer device, orient the protractor wheel on the test port so that the  $^{\circ}$  mark is aligned with the longitudinal axis of the wind tunnel duct. Maintaining this alignment, lock the wheel into place on the wind tunnel test port. Align the scribe line on the pointer collar with the reference scribe line or with a mark aligned with the reference scribe line, as determined under section 18.1.1.1. Maintaining this rotational alignment, lock the pointer device onto the probe sheath.

18.4.2.2 Zero the pressure-measuring device used for yaw nulling.

18.4.2.3 Insert the probe assembly into the wind tunnel through the entry port, positioning the probe's impact port at the calibration location. Check the responsiveness of the pressure-measuring device to probe rotation, taking corrective action if the response is unacceptable.

18.4.2.4 Ensure that the probe is in a horizontal position using a carpenter's level.

18.4.2.5 Rotate the probe either clockwise or counterclockwise until a yaw null [zero  $\Delta P$ for a Type S probe or zero (P<sub>2</sub>–P<sub>3</sub>) for a 3– D probe] is obtained. If using a Type S probe with an attached thermocouple, the direction of the probe rotation shall be such that the thermocouple is located downstream of the probe pressure ports at the yaw-null position.

18.4.2.6 Read and record the value of  $\theta_{null}$ , the angle indicated by the anglemeasuring device at the yaw-null position. Record the angle reading on a form similar to Table 2G–6. Do not associate an algebraic sign with this reading.

18.4.2.7 Determine the magnitude and algebraic sign of the reference scribe line rotational offset,  $R_{SLO}$ . The magnitude of  $R_{SLO}$  will be equal to either  $\theta_{null}$  or (90°– $\theta_{null}$ ), depending on the type of probe being calibrated and the type of angle-measuring device used. (See Table 2G–7 for a summary.) The algebraic sign of  $R_{SLO}$  will either be positive if the rotational position of the reference scribe line is clockwise or negative if counterclockwise with respect to the probe's yaw-null position. Figure 2G–10 illustrates how the magnitude and sign of  $R_{SLO}$  are determined.

18.4.2.8 Perform the steps in sections 18.3.2.3 through 18.3.2.7 twice at each of the two calibration velocities selected for the

probe under section 10.6. Record the values of  $R_{\rm SLO}$  in a form similar to Table 2G–6.

18.4.2.9 The average of all  $R_{\rm SLO}$  values is the reference scribe line rotational offset for the probe.

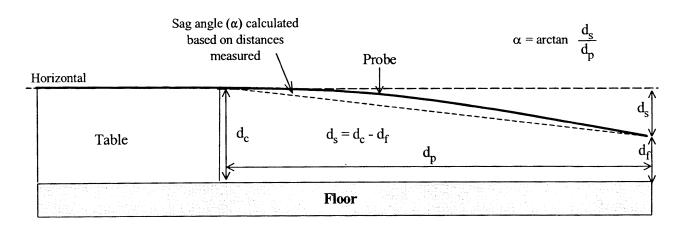

Figure 2G-6. Elements in horizontal straightness test based on trigonometry.

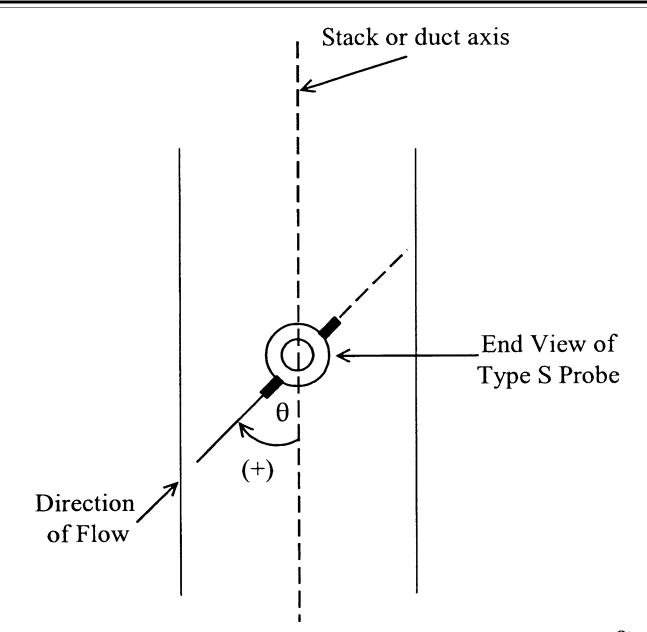

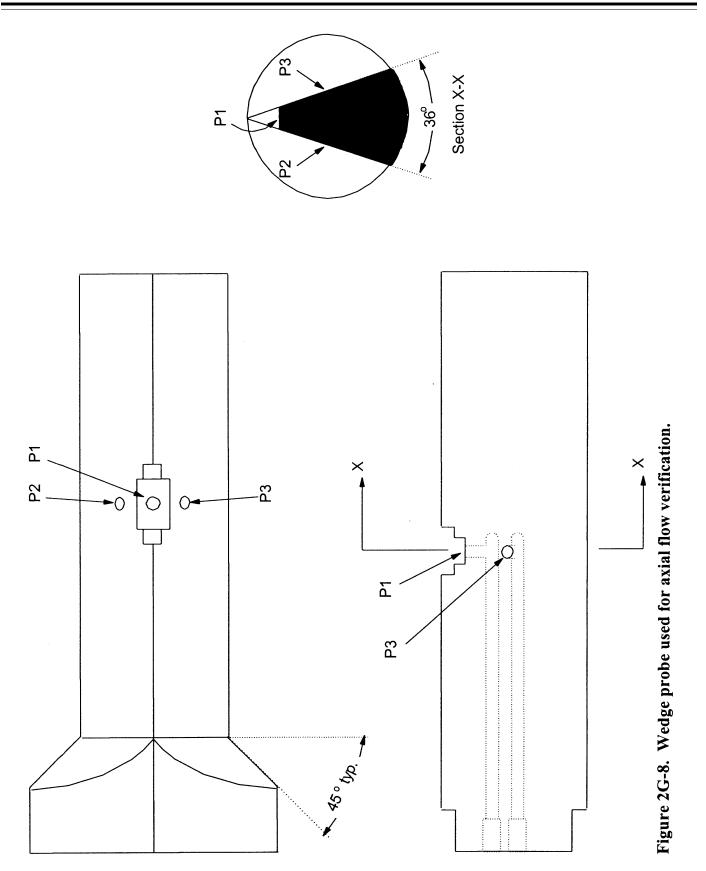

Figure 2G-7. Sign convention for the measured angle ( $\theta$ ) when the probe impact port is pointed directly into the flow. The angle  $\theta$  is positive when the probe's impact pressure port is oriented in a clockwise rotational position relative to the stack or duct axis, as shown above, and negative for a counterclockwise orientation.

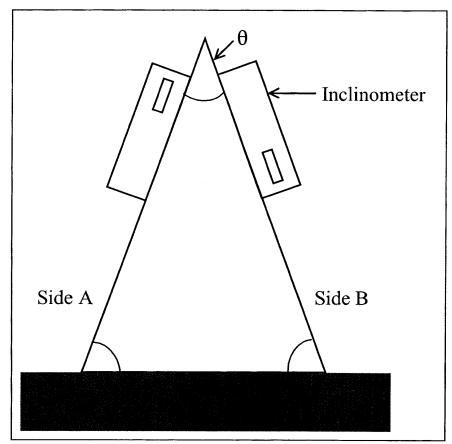

Figure 2G-9. Triangular block used for digital inclinometer calibration.

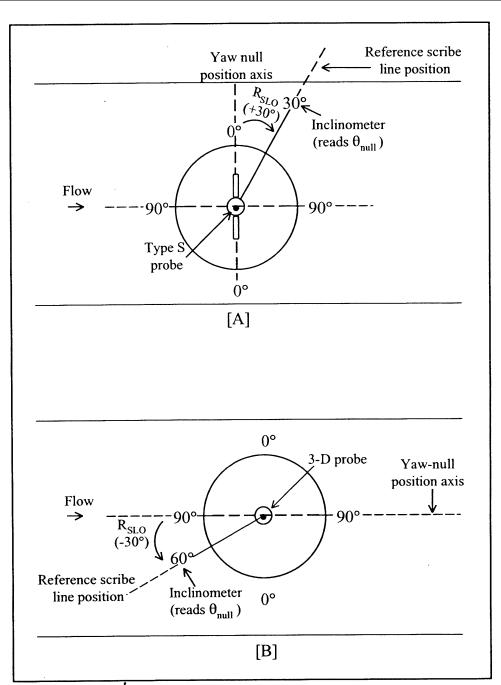

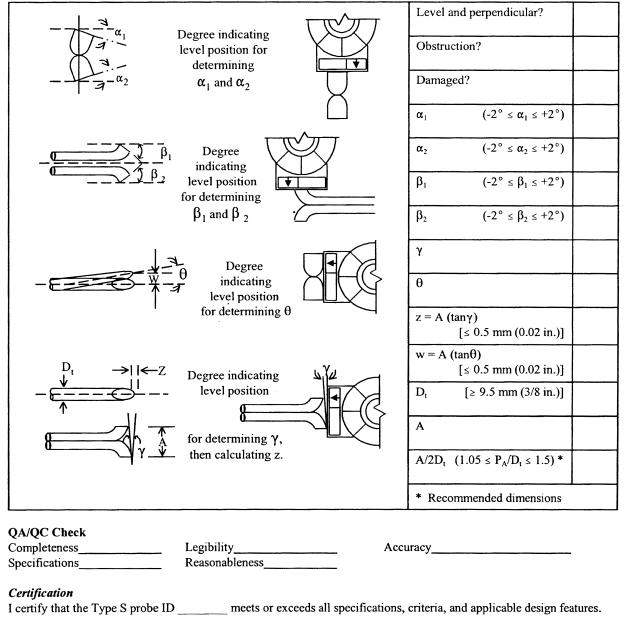

Figure 2G-10. Determination of reference scribe line rotational offset ( $R_{SLO}$ ) in a horizontal wind tunnel with axial flow for: [A], a Type S probe, and [B], a 3-D probe. In [A] and [B], the probe impact pressure port is aligned with the yaw-null position axis and the inclinometer reads  $\theta_{null}$ . In [A], the magnitude of  $R_{SLO} = \theta_{null}$  and the sign is positive (clockwise from yaw-null position axis). In [B], the magnitude of  $R_{SLO} = 90^{\circ}-\theta_{null}$  and the sign is negative (counterclockwise from yaw-null position axis).

## Table 2G-1. Type S Probe Inspection Sheet

**Note:** Method 2 provides the criteria for an acceptably constructed Type S pitot tube. However, the procedure for making the necessary measurements is not specified. One approach is given below.

- 1. Use a vise with parallel and perpendicular faces. Use an angle-measuring device (analog or digital) for this check.
- 2. Place the pitot tube in the vise, and level the pitot tube horizontally using the angle-measuring device.
- 3. Place the angle-measuring device as shown below.
- 4. Measure distance A, which is  $P_A$  plus  $P_B$ . Method 2 specifies that  $P_A = P_B$ , but provides no tolerance for this measurement. Because this measurement is very difficult, it is suggested that  $P_A = P_B = A/2$ .
- 5. Measure the external tube diameter (D<sub>i</sub>) with a micrometer, machinist's rule, or internal caliper.
- 6. Record all data as shown on the form below.
- 7. Calculate dimensions w and z as shown below.

## Method 2H—Determination of Stack Gas Velocity Taking Into Account Velocity Decay Near the Stack Wall

## 1.0 Scope and Application

1.1 This method is applicable in conjunction with Methods 2, 2F, and 2G (40 CFR Part 60, Appendix A) to account for velocity decay near the wall in circular stacks and ducts.

1.2 This method is not applicable for testing stacks and ducts less than 3.3 ft (1.0 m) in diameter.

1.3 Data Quality Objectives. Adherence to the requirements of this method will enhance the quality of the data obtained from air pollutant sampling methods.

#### 2.0 Summary of Method

2.1 A wall effects adjustment factor is determined. It is used to adjust the average stack gas velocity obtained under Method 2, 2F, or 2G of this appendix to take into account velocity decay near the stack or duct wall.

2.2 The method contains two possible procedures: a calculational approach which derives an adjustment factor from velocity measurements and a default procedure which assigns a generic adjustment factor based on the construction of the stack or duct.

2.2.1 The calculational procedure derives a wall effects adjustment factor from velocity measurements taken using Method 2, 2F, or 2G at 16 (or more) traverse points specified under Method 1 of this appendix and a total of eight (or more) wall effects traverse points specified under this method. The calculational procedure based on velocity measurements is not applicable for horizontal circular ducts where build-up of particulate matter or other material in the bottom of the duct is present.

2.2.2 A default wall effects adjustment factor of 0.9900 for brick and mortar stacks and 0.9950 for all other types of stacks and ducts may be used without taking wall effects measurements in a stack or duct.

2.3 When the calculational procedure is conducted as part of a relative accuracy test audit (RATA) or other multiple-run test procedure, the wall effects adjustment factor derived from a single traverse (i.e., single RATA run) may be applied to all runs of the same RATA without repeating the wall effects measurements. Alternatively, wall effects adjustment factors may be derived for several traverses and an average wall effects adjustment factor applied to all runs of the same RATA.

3.0 Definitions.

3.1 Complete wall effects traverse means a traverse in which measurements are taken at  $d_{rem}$  (see section 3.3) and at 1-in. intervals in each of the four Method 1 equal-area sectors closest to the wall, beginning not farther than 4 in. (10.2 cm) from the wall and extending either (1) across the entire width of the Method 1 equal-area sector or (2) for stacks or ducts where this width exceeds 12 in. (30.5 cm) (i.e., stacks or ducts greater than or equal to 15.6 ft [4.8 m] in diameter), to a distance of not less than 12 in. (30.5 cm) from the wall. Note: Because this method specifies that measurements must be taken at whole number multiples of 1 in. from a stack or

duct wall, for clarity numerical quantities in this method are expressed in English units followed by metric units in parentheses. To enhance readability, hyphenated terms such as "1-in. intervals" or "1-in. incremented," are expressed in English units only.

3.2  $d_{last}$ . Depending on context,  $d_{last}$  means either (1) the distance from the wall of the last 1-in. incremented wall effects traverse point or (2) the traverse point located at that distance (see Figure 2H–2).

3.3  $d_{rem}$ . Depending on context,  $d_{rem}$  means either (1) the distance from the wall of the centroid of the area between  $d_{last}$  and the interior edge of the Method 1 equal-area sector closest to the wall or (2) the traverse point located at that distance (see Figure 2H-2).

3.4 *"May," "Must," "Shall," "Should,"* and the imperative form of verbs.

3.4.1 *"May"* is used to indicate that a provision of this method is optional.

3.4.2 *"Must," "Shall,"* and the imperative form of verbs (such as "record" or "enter") are used to indicate that a provision of this method is mandatory.

3.4.3 *"Should"* is used to indicate that a provision of this method is not mandatory but is highly recommended as good practice.

3.5 *Method* 1 refers to 40 CFR part 60, appendix A, "Method 1—Sample and velocity traverses for stationary sources."

3.6 Method 1 exterior equal-area sector and Method 1 equal-area sector closest to the wall mean any one of the four equal-area sectors that are closest to the wall for a circular stack or duct laid out in accordance with section 2.3.1 of Method 1 (see Figure 2H–1).

3.7 *Method 1 interior equal-area sector* means any of the equal-area sectors other than the Method 1 exterior equal-area sectors (as defined in section 3.6) for a circular stack or duct laid out in accordance with section 2.3.1 of Method 1 (see Figure 2H–1).

3.8 Method 1 traverse point and Method 1 equal-area traverse point mean a traverse point located at the centroid of an equal-area sector of a circular stack laid out in accordance with section 2.3.1 of Method 1.

3.9 *Method 2* refers to 40 CFR part 60, appendix A, "Method 2—Determination of stack gas velocity and volumetric flow rate (Type S pitot tube)."

3.10 *Method 2F* refers to 40 CFR part 60, appendix A, "Method 2F—Determination of stack gas velocity and volumetric flow rate with three-dimensional probes."

3.11 *Method 2G* refers to 40 CFR part 60, appendix A, "Method 2G—Determination of stack gas velocity and volumetric flow rate with two-dimensional probes."

3.12 1-in. incremented wall effects traverse point means any of the wall effects traverse points that are located at 1-in. intervals, i.e., traverse points  $d_1$  through  $d_{last}$  (see Figure 2H–2).

3.13 Partial wall effects traverse means a traverse in which measurements are taken at fewer than the number of traverse points required for a "complete wall effects traverse" (as defined in section 3.1), but are taken at a minimum of two traverse points in each Method 1 equal-area sector closest to the wall, as specified in section 8.2.2.

3.14 *Relative accuracy test audit (RATA)* is a field test procedure performed in a stack

or duct in which a series of concurrent measurements of the same stack gas stream is taken by a reference method and an installed monitoring system. A RATA usually consists of series of 9 to 12 sets of such concurrent measurements, each of which is referred to as a RATA run. In a volumetric flow RATA, each reference method run consists of a complete traverse of the stack or duct.

3.15 Wall effects-unadjusted average velocity means the average stack gas velocity, not accounting for velocity decay near the wall, as determined in accordance with Method 2, 2F, or 2G for a Method 1 traverse consisting of 16 or more points.

3.16 Wall effects-adjusted average velocity means the average stack gas velocity, taking into account velocity decay near the wall, as calculated from measurements at 16 or more Method 1 traverse points and at the additional wall effects traverse points specified in this method.

3.17 *Wall effects traverse point* means a traverse point located in accordance with sections 8.2.2 or 8.2.3 of this method.

4.0 Interferences. [Reserved]

### 5.0 Safety

5.1 This method may involve hazardous materials, operations, and equipment. This method does not purport to address all of the health and safety considerations associated with its use. It is the responsibility of the user of this method to establish appropriate health and safety practices and to determine the applicability of occupational health and safety regulatory requirements prior to performing this method.

## 6.0 Equipment and Supplies

6.1 The provisions pertaining to equipment and supplies in the method that is used to take the traverse point measurements (i.e., Method 2, 2F, or 2G) are applicable under this method.

7.0 Reagents and Standards. [Reserved]

## 8.0 Sample Collection and Analysis

8.1 Default Wall Effects Adjustment Factors. A default wall effects adjustment factor of 0.9900 for brick and mortar stacks and 0.9950 for all other types of stacks and ducts may be used without conducting the following procedures.

8.2 Traverse Point Locations. Determine the location of the Method 1 traverse points in accordance with section 8.2.1 and the location of the traverse points for either a partial wall effects traverse in accordance with section 8.2.2 or a complete wall effects traverse in accordance with section 8.2.3.

8.2.1 Method 1 equal-area traverse point locations. Determine the location of the Method 1 equal-area traverse points for a traverse consisting of 16 or more points using Table 1–2 (Location of Traverse Points in Circular Stacks) of Method 1.

8.2.2 Partial wall effects traverse. For a partial wall effects traverse, measurements must be taken at a minimum of the following two wall effects traverse point locations in all four Method 1 equal-area sectors closest to the wall: (1) 1 in. (2.5 cm) from the wall (except as provided in section 8.2.2.1) and (2)

 $d_{\rm rem,}$  as determined using Equation 2H–1 or 2H–2 (see section 8.2.2.2).

8.2.2.1 If the probe cannot be positioned at 1 in. (2.5 cm) from the wall (e.g., because of insufficient room to withdraw the probe shaft) or if velocity pressure cannot be detected at 1 in. (2.5 cm) from the wall (for any reason other than build-up of particulate matter in the bottom of a duct), take measurements at the 1-in. incremented wall effects traverse point closest to the wall where the probe can be positioned and velocity pressure can be detected.

8.2.2.2 Calculate the distance of  $d_{rem}$  from the wall to within  $\pm^{1}/_{4}$  in. (6.4 mm) using Equation 2H–1 or Equation 2H–2 (for a 16-point traverse).

For a 16-point Method 1 traverse, Equation

$$d_{\text{last}} \leq d_{b}$$

Eq. 2H-3

2H-1 becomes:

Where:

- r = the stack or duct radius determined from direct measurement of the stack or duct diameter in accordance with section 8.6 of Method 2F or Method 2G, in. (cm);
- p = the number of Method 1 equal-area traverse points on a diameter,  $p \ge 8$  (e.g., for a 16-point traverse, p = 8);  $d_{last}$  and  $d_{rem}$  are defined in sections 3.2 and 3.3 respectively, in. (cm).

$$d_{rem} = r - \sqrt{\frac{7}{8}r^2 - rd_{last} + \frac{1}{2}d_{last}^2}$$
 Eq. 2H-2

8.2.2.3 Measurements may be taken at any number of additional wall effects traverse points, with the following provisions.

(a)  $d_{last}$  must not be closer to the center of the stack or duct than the distance of the interior edge (boundary),  $d_b$ , of the Method 1 equal-area sector closest to the wall (see Figure 2H–2 or 2H–3). That is,

$$d_{b} = r \left( 1 - \sqrt{1 - \frac{2}{p}} \right) \qquad \text{Eq. 2H-4}$$

Where:

$$d_{b} = r \left( 1 - \sqrt{1 - \frac{2}{p}} \right) \qquad \text{Eq. 2H-4}$$

Table 2H–1 shows  $d_b$  as a function of the stack or duct radius, r, for traverses ranging from 16 to 48 points (i.e., for values of p ranging from 8 to 24).

 $(\bar{b})$  Each point must be located at a distance that is a whole number (e.g., 1, 2, 3) multiple of 1 in. (2.5 cm).

(c) Points do not have to be located at consecutive 1-in. intervals. That is, one or more 1-in. incremented points may be skipped. For example, it would be acceptable for points to be located at 1 in. (2.5 cm), 3 in. (7.6 cm), 5 in. (12.7 cm),  $d_{last}$ , and  $d_{rem}$ ; or at 1 in. (2.5 cm), 2 in. (5.1 cm), 4 in. (10.2 cm), 7 in. (17.8 cm),  $d_{last}$ , and  $d_{rem}$ . Follow the instructions in section 8.7.1.2 of this method for recording results for wall effects traverse points that are skipped. It should be noted that the full extent of velocity decay may not be accounted for if measurements are not taken at all 1-in. incremented points close to the wall.

8.2.3 Complete wall effects traverse. For a complete wall effects traverse, measurements must be taken at the following points in all four Method 1 equal-area sectors closest to the wall.

(a) The 1-in. incremented wall effects traverse point closest to the wall where the probe can be positioned and velocity can be detected, but no farther than 4 in. (10.2 cm) from the wall.

(b) Every subsequent 1-in. incremented wall effects traverse point out to the interior edge of the Method 1 equal-area sector or to 12 in. (30.5 cm) from the wall, whichever comes first. Note: In stacks or ducts with diameters greater than 15.6 ft (4.8 m) the interior edge of the Method 1 equal-area sector is farther from the wall than 12 in. (30.5 cm).

(c)  $d_{\rm rem}$ , as determined using Equation 2H–1 or 2H–2 (as applicable). Note: For a complete traverse of a stack or duct with a diameter less than 16.5 ft (5.0 m), the distance between  $d_{\rm rem}$  and  $d_{\rm last}$  is less than or equal to  $\frac{1}{2}$  in. (12.7 mm). As discussed in section 8.2.4.2, when the distance between  $d_{\rm rem}$  and  $d_{\rm last}$  is less than or equal to  $\frac{1}{2}$  in. (12.7 mm), the velocity measured at  $d_{\rm last}$  may be used for  $d_{\rm rem}$ . Thus, it is not necessary to calculate the distance of  $d_{\rm rem}$  or to take measurements at  $d_{\rm rem}$  when conducting a complete traverse of a stack or duct with a diameter less than 16.5 ft (5.0 m).

8.2.4 Special considerations. The following special considerations apply when the distance between traverse points is less than or equal to  $\frac{1}{2}$  in. (12.7 mm).

8.2.4.1 A wall effects traverse point and the Method 1 traverse point. If the distance between a wall effects traverse point and the Method 1 traverse point is less than or equal to  $\frac{1}{2}$  in. (12.7 mm), taking measurements at both points is allowed but not required or recommended; if measurements are taken at only one point, take the measurements at the point that is farther from the wall and use the velocity obtained at that point as the value for both points (see sections 8.2.3 and 9.2 for related requirements).

8.2.4.2  $d_{\text{rem}}$  and  $d_{\text{last}}$ . If the distance between  $d_{\text{rem}}$  and  $d_{\text{last}}$  is less than or equal to  $\frac{1}{2}$  in. (12.7 mm), taking measurements at  $d_{\text{rem}}$  is allowed but not required or recommended; if measurements are not taken at  $d_{\text{rem}}$ , the measured velocity value at  $d_{\text{last}}$ must be used as the value for both  $d_{\text{last}}$  and  $d_{\text{rem}}$ .

8.3 Traverse Point Sampling Order and Probe Selection. Determine the sampling order of the Method 1 and wall effects traverse points and select the appropriate probe for the measurements, taking into account the following considerations.

**8.3.1** Traverse points on any radius may be sampled in either direction (i.e., from the wall toward the center of the stack or duct, or vice versa).

**8.3.2** To reduce the likelihood of velocity variations during the time of the traverse and the attendant potential impact on the wall effects-adjusted and unadjusted average velocities, the following provisions of this method shall be met.

8.3.2.1 Each complete set of Method 1 and wall effects traverse points accessed from the same port shall be sampled without interruption. Unless traverses are performed simultaneously in all ports using separate probes at each port, this provision disallows first sampling all Method 1 points at all ports and then sampling all the wall effects points.

**8.3.2.2** The entire integrated Method 1 and wall effects traverse across all test ports shall be as short as practicable, consistent with the measurement system response time (see section 8.4.1.1) and sampling (see section 8.4.1.2) provisions of this method.

8.3.3 It is recommended but not required that in each Method 1 equal-area sector closest to the wall, the Method 1 equal-area traverse point should be sampled in sequence between the adjacent wall effects traverse points. For example, for the traverse point configuration shown in Figure 2H-2, it is recommended that the Method 1 equal-area traverse point be sampled between  $d_{\text{last}}$  and  $d_{\rm rem}$ . In this example, if the traverse is conducted from the wall toward the center of the stack or duct, it is recommended that measurements be taken at points in the following order:  $d_1$ ,  $d_2$ ,  $d_{\text{last}}$ , the Method 1 traverse point,  $d_{\rm rem}$ , and then at the traverse points in the three Method 1 interior equalarea sectors.

8.3.4 The same type of probe must be used to take measurements at all Method 1 and wall effects traverse points. However, different copies of the same type of probe may be used at different ports (e.g., Type S probe 1 at port A, Type S probe 2 at port B) 26556

or at different traverse points accessed from a particular port (e.g., Type S probe 1 for Method 1 interior traverse points accessed from port A, Type S probe 2 for wall effects traverse points and the Method 1 exterior traverse point accessed from port A). The identification number of the probe used to obtain measurements at each traverse point must be recorded.

8.4 Measurements at Method 1 and Wall Effects Traverse Points. Conduct measurements at Method 1 and wall effects traverse points in accordance with Method 2, 2F, or 2G and in accordance with the provisions of the following subsections (some of which are included in Methods 2F and 2G but not in Method 2), which are particularly important for wall effects testing.

8.4.1 Probe residence time at wall effects traverse points. Due to the steep temperature and pressure gradients that can occur close to the wall, it is very important for the probe residence time (i.e., the total time spent at a traverse point) to be long enough to ensure collection of representative temperature and pressure measurements. The provisions of Methods 2F and 2G in the following subsections shall be observed.

8.4.1.1 System response time. Determine the response time of each probe measurement system by inserting and positioning the "cold" probe (at ambient temperature and pressure) at any Method 1 traverse point. Read and record the probe differential pressure, temperature, and elapsed time at 15-second intervals until stable readings for both pressure and temperature are achieved. The response time is the longer of these two elapsed times. Record the response time.

8.4.1.2 Sampling. At the start of testing in each port (i.e., after a probe has been inserted into the stack gas stream), allow at least the response time to elapse before beginning to take measurements at the first traverse point accessed from that port. Provided that the probe is not removed from the stack gas stream, measurements may be taken at subsequent traverse points accessed from the same test port without waiting again for the response time to elapse.

8.4.2 Temperature measurement for wall effects traverse points. Either (1) take temperature measurements at each wall effects traverse point in accordance with the applicable provisions of Method 2, 2F, or 2G; or (2) use the temperature measurement at the Method 1 traverse point closest to the wall as the temperature measurement for all the wall effects traverse points in the corresponding equal-area sector.

8.4.3 Non-detectable velocity pressure at wall effects traverse points. If the probe cannot be positioned at a wall effects traverse point or if no velocity pressure can be detected at a wall effects point, measurements shall be taken at the first subsequent wall effects traverse point farther from the wall where velocity can be detected. Follow the instructions in section 8.7.1.2 of this method for recording results for wall effects traverse points where velocity pressure cannot be detected. It should be noted that the full extent of velocity decay may not be accounted for if measurements are not taken at the 1-in. incremented wall effects traverse points closest to the wall.

8.5 Data Recording. For each wall effects and Method 1 traverse point where measurements are taken, record all pressure, temperature, and attendant measurements prescribed in section 3 of Method 2 or section 8.0 of Method 2F or 2G, as applicable.

8.6 Point Velocity Calculation. For each wall effects and Method 1 traverse point, calculate the point velocity value  $(v_i)$  in accordance with sections 12.1 and 12.2 of Method 2F for tests using Method 2F and in accordance with sections 12.1 and 12.2 of Method 2G for tests using Method 2 and Method 2G. (Note that the term  $(v_i)$  in this method corresponds to the term  $(v_{a(i)})$  in Methods 2F and 2G.) When the equations in the indicated sections of Method 2G are used in deriving point velocity values for Method 2 tests, set the value of the yaw angles appearing in the equations to 0°.

8.7 Tabulating Calculated Point Velocity Values for Wall Effects Traverse Points. Enter the following values in a hardcopy or electronic form similar to Form 2H-1 (for 16point Method 1 traverses) or Form 2H-2 (for Method 1 traverses consisting of more than 16 points). A separate form must be completed for each of the four Method 1 equal-area sectors that are closest to the wall. (a) Port ID (e.g., A, B, C, or D) (b) Probe type

(c) Probe ID

- (d) Stack or duct diameter in ft (m) (determined in accordance with section 8.6 of Method 2F or Method 2G)
- (e) Stack or duct radius in in. (cm) (f) Distance from the wall of wall effects traverse points at 1-in. intervals, in ascending order starting with 1 in. (2.5 cm) (column A of Form 2H-1 or 2H-2)
- (g) Point velocity values  $(v_d)$  for 1-in. incremented traverse points (see section 8.7.1), including  $d_{last}$  (see section 8.7.2)
- (h) Point velocity value (v<sub>drem</sub>) at d<sub>rem</sub> (see section 8.7.3).

8.7.1 Point velocity values at wall effects traverse points other than dlast. For every 1 in. incremented wall effects traverse point other than dlast, enter in column B of Form 2H-1 or 2H-2 either the velocity measured at the point (see section 8.7.1.1) or the velocity measured at the first subsequent traverse point farther from the wall (see section 8.7.1.2). A velocity value must be entered in column B of Form 2H-1 or 2H-2 for every 1-in. incremented traverse point from  $d_1$  (representing the wall effects traverse point 1 in. [2.5 cm] from the wall) to  $d_{last}$ 

8.7.1.1 For wall effects traverse points where the probe can be positioned and velocity pressure can be detected, enter the value obtained in accordance with section 8.6

8.7.1.2 For wall effects traverse points that were skipped [see section 8.2.2.3(c)] and for points where the probe cannot be positioned or where no velocity pressure can be detected, enter the value obtained at the first subsequent traverse point farther from the wall where velocity pressure was detected and measured and follow the entered value with a "flag," such as the notation "NM," to indicate that "no measurements" were actually taken at this point.

8.7.2 Point velocity value at  $d_{last}$ . For  $d_{last}$ , enter in column B of Form 2H-1 or 2H-2 the

measured value obtained in accordance with section 8.6.

8.7.3 Point velocity value (*v*<sub>drem</sub>) at *d*<sub>rem</sub>. Enter the point velocity value obtained at drem in column G of row 4a in Form 2H-1 or 2H–2. If the distance between  $d_{rem}$  and  $d_{last}$ is less than or equal to 1/2 in. (12.7 mm), the measured velocity value at  $d_{last}$  may be used as the value at  $d_{rem}$  (see section 8.2.4.2).

9.0 Quality Control.

9.1 Particulate Matter Build-up in Horizontal Ducts. Wall effects testing of horizontal circular ducts should be conducted only if build-up of particulate matter or other material in the bottom of the duct is not present.

9.2 Verifying Traverse Point Distances. In taking measurements at wall effects traverse points, it is very important for the probe impact pressure port to be positioned as close as practicable to the traverse point locations in the gas stream. For this reason, before beginning wall effects testing, it is important to calculate and record the traverse point positions that will be marked on each probe for each port, taking into account the distance that each port nipple (or probe mounting flange for automated probes) extends out of the stack and any extension of the port nipple (or mounting flange) into the gas stream. To ensure that traverse point positions are properly identified, the following procedures should be performed on each probe used.

9.2.1 Manual probes. Mark the probe insertion distance of the wall effects and Method 1 traverse points on the probe sheath so that when a mark is aligned with the outside face of the stack port, the probe impact port is located at the calculated distance of the traverse point from the stack inside wall. The use of different colored marks is recommended for designating the wall effects and Method 1 traverse points. Before the first use of each probe, check to ensure that the distance of each mark from the center of the probe impact pressure port agrees with the previously calculated traverse point positions to within  $\pm \frac{1}{4}$  in. (6.4 mm).

9.2.2 Automated probe systems. For automated probe systems that mechanically position the probe head at prescribed traverse point positions, activate the system with the probe assemblies removed from the test ports and sequentially extend the probes to the programmed location of each wall effects traverse point and the Method 1 traverse points. Measure the distance between the center of the probe impact pressure port and the inside of the probe assembly mounting flange for each traverse point. The measured distances must agree with the previously calculated traverse point positions to within ±1/4 in. (6.4 mm).

9.3 Probe Installation. Properly sealing the port area is particularly important in taking measurements at wall effects traverse points. For testing involving manual probes, the area between the probe sheath and the port should be sealed with a tightly fitting flexible seal made of an appropriate material such as heavy cloth so that leakage is minimized. For automated probe systems, the probe assembly mounting flange area should be checked to verify that there is no leakage.

9.4 Velocity Stability. This method should be performed only when the average gas velocity in the stack or duct is relatively constant over the duration of the test. If the average gas velocity changes significantly during the course of a wall effects test, the test results should be discarded.

#### 10.0 Calibration

10.1 The calibration coefficient(s) or curves obtained under Method 2, 2F, or 2G and used to perform the Method 1 traverse are applicable under this method.

### 11.0 Analytical Procedure

11.1 Sample collection and analysis are concurrent for this method (see section 8).

#### 12.0 Data Analysis and Calculations

12.1 The following calculations shall be performed to obtain a wall effects adjustment factor (*WAF*) from (1) the wall effectsunadjusted average velocity ( $v_{avg}$ ), (2) the replacement velocity ( $\hat{v}_{ej}$ ) for each of the four Method 1 sectors closest to the wall, and (3) the average stack gas velocity that accounts for velocity decay near the wall ( $\hat{v}_{avg}$ ).

12.2 Nomenclature. The following terms are listed in the order in which they appear in Equations 2H–5 through 2H–21.

- $v_{avg}$ =the average stack gas velocity, unadjusted for wall effects, actual ft/sec (m/sec);
- vi<sub>i</sub>=stack gas point velocity value at Method 1 interior equal-area sectors, actual ft/sec (m/sec);
- vej=stack gas point velocity value, unadjusted for wall effects, at Method 1 exterior equalarea sectors, actual ft/sec (m/sec);
- i=index of Method 1 interior equal-area traverse points;
- *j*=index of Method 1 exterior equal-area traverse points;
- *n*=total number of traverse points in the Method 1 traverse;
- *vdec*<sub>d</sub>=the wall effects decay velocity for a sub-sector located between the traverse points at distances d-1 (in metric units, d-2.5) and d from the wall, actual ft/sec (m/sec);
- $v_d$ =the measured stack gas velocity at distance d from the wall, actual ft/sec (m/ sec); Note:  $v_0$ =0;
- d=the distance of a 1-in. incremented wall effects traverse point from the wall, for traverse points  $d_l$  through  $d_{last}$ , in. (cm);
- $A_d$ =the cross-sectional area of a sub-sector located between the traverse points at distances d-1 (in metric units, d-2.5) and d from the wall, in.<sup>2</sup> (cm<sup>2</sup>) (e.g., sub-sector  $A_2$  shown in Figures 2H–3 and 2H–4);

*r*=the stack or duct radius, in. (cm);

 $Q_d$ =the stack gas volumetric flow rate for a sub-sector located between the traverse

For each line in column A of Form 2H-1 or

2H-2 that contains a value of d, enter the

value of the expression  $\frac{1}{4} \pi (r - d + 1)^2$  in

column F. Note that Equation 2H-8 is

column D, the value of the expression 1/4

 $\pi(r-d)^2$  in column E, and the value of  $A_d$  in

designed for use only with English units (in.).

If metric units (cm) are used, the first term,

points at distances d-1 (in metric units, d-2.5) and d from the wall, actual ft-in.<sup>2</sup>/ sec (m-cm <sup>2</sup>/sec);

- $U_{d} \rightarrow d\lambda \alpha \sigma \tau$ =the total stack gas volumetric flow rate for all sub-sectors located between the wall and  $d_{last}$ , actual ft-in.<sup>2</sup>/sec (m-cm<sup>2</sup>/sec);
- $d_{last}$ =the distance from the wall of the last 1in. incremented wall effects traverse point, in. (cm);
- $A_{drem}$ =the cross-sectional area of the subsector located between  $d_{iast}$  and the interior edge of the Method 1 equal-area sector closest to the wall, in.<sup>2</sup> (cm<sup>2</sup>) (see Figure 2H–4);
- *p*=the number of Method 1 traverse points per diameter, *p*≥8 (e.g., for a 16-point traverse, *p*=8);
- $d_{rem}$ =the distance from the wall of the centroid of the area between  $d_{last}$  and the interior edge of the Method 1 equal-area sector closest to the wall, in. (cm);
- $Q_{drem}$ =the total stack gas volumetric flow rate for the sub-sector located between  $d_{last}$  and the interior edge of the Method 1 equalarea sector closest to the wall, actual ftin.<sup>2</sup>/sec (m-cm<sup>2</sup>/sec);
- $v_{drem}$ =the measured stack gas velocity at distance  $d_{rem}$  from the wall, actual ft/sec (m/sec);
- $Q_T$ =the total stack gas volumetric flow rate for the Method 1 equal-area sector closest to the wall, actual ft-in.<sup>2</sup>/sec (m-cm<sup>2</sup>/sec);
- $\hat{v}_{ej}$ =the replacement stack gas velocity for the Method 1 equal-area sector closest to the wall, i.e., the stack gas point velocity value, adjusted for wall effects, for the j<sup>th</sup> Method 1 equal-area sector closest to the wall, actual ft/sec (m/sec);
- $\hat{v}_{avg}$ =the average stack gas velocity that accounts for velocity decay near the wall, actual ft/sec (m/sec);
- *WAF*=the wall effects adjustment factor derived from  $v_{avg}$  and  $\hat{v}_{avg}$  for a single traverse, dimensionless;
- $\hat{v}_{final}$ =the final wall effects-adjusted average stack gas velocity that replaces the unadjusted average stack gas velocity obtained using Method 2, 2F, or 2G for a field test consisting of a single traverse, actual ft/sec (m/sec);
- *WAF*=the wall effects adjustment factor that is applied to the average velocity, unadjusted for wall effects, in order to obtain the final wall effects-adjusted stack gas velocity,  $\hat{v}_{final}$  or,  $\hat{v}_{final(k)}$ , dimensionless;
- $\hat{v}_{final(k)}$ =the final wall effects-adjusted average stack gas velocity that replaces the unadjusted average stack gas velocity obtained using Method 2, 2F, or 2G on run *k* of a RATA or other multiple-run field test procedure, actual ft/sec (m/sec);

$$A_d = \frac{1}{4}\pi(r-d+1)^2 - \frac{1}{4}\pi(r-d)^2$$
 Eq. 2H-8

 $^{1\!/_4}\pi(r-d+1)^2,$  must be changed to  $^{1\!/_4}\pi(r-d+2.5)^2.$  This change must also be made in column D of Form 2H–1 or 2H–2.

12.4.3 Calculate the volumetric flow through each cross-sectional area derived in section 12.4.2 by multiplying the values of  $vdec_d$ , derived according to section 12.4.1, by

- $\hat{v}_{avg(k)}$ =the average stack gas velocity, obtained on run *k* of a RATA or other multiple-run procedure, unadjusted for velocity decay near the wall, actual ft/sec (m/sec);
- *k*=index of runs in a RATA or other multiplerun procedure.

12.3 Calculate the average stack gas velocity that does not account for velocity decay near the wall ( $v_{avg}$ ) using Equation 2H–5.

$$v_{avg} = \frac{\left(\sum_{i=1}^{n-4} vi_i + \sum_{j=1}^{4} ve_j\right)}{n}$$
 Eq. 2H-5

(Note that  $v_{avg}$  in Equation 2H–5 is the same as  $v_{(a)avg}$  in Equations 2F–9 and 2G–8 in Methods 2F and 2G, respectively.)

For a 16-point traverse, Equation 2H–5 may be written as follows:

$$v_{avg} = \frac{\left(\sum_{i=1}^{12} vi_i + \sum_{j=1}^{4} ve_j\right)}{16}$$
 Eq. 2H-6

12.4 Calculate the replacement velocity,  $\hat{v}_{ej}$ , for each of the four Method 1 equal-area sectors closest to the wall using the procedures described in sections 12.4.1 through 12.4.8. Forms 2H–1 and 2H–2 provide sample tables that may be used in either hardcopy or spreadsheet format to perform the calculations described in sections 12.4.1 through 12.4.8. Forms 2H–3 and 2H–4 provide examples of Form 2H–1 filled in for partial and complete wall effects traverses.

12.4.1 Calculate the average velocity (designated the "decay velocity," vdec<sub>d</sub>) for each sub-sector located between the wall and  $d_{\text{last}}$  (see Figure 2H–3) using Equation 2H–7.

$$vdec_{d} = \frac{v_{d-1} + v_{d}}{2}$$
 Eq. 2H-7

For each line in column A of Form 2H–1 or 2H–2 that contains a value of d, enter the corresponding calculated value of  $vdec_d$  in column C.

12.4.2 Calculate the cross-sectional area between the wall and the first 1-in. incremented wall effects traverse point and between successive 1-in. incremented wall effects traverse points, from the wall to  $d_{\text{last}}$ (see Figure 2H–3), using Equation 2H–8.

the cross-sectional areas derived in section 12.4.2 using Equation 2H-9.

$$Q_d = vdec_d \times A_d$$
 Eq. 2H-9

For each line in column A of Form 2H–1 or 2H–2 that contains a value of d, enter the corresponding calculated value of  $Q_d$  in column G.

12.4.4 Calculate the total volumetric flow through all sub-sectors located between the wall and  $d_{last}$ , using Equation 2H–10.

$$Q_{d_1-d_{last}} = \sum_{d=1}^{d_{last}} Q_d$$
 Eq. 2H-10

Enter the calculated value of  $Q_{d1} \rightarrow_{dlast}$  in line 3 of column G of Form 2H–1 or 2H–2.

12.4.5 Calculate the cross-sectional area of the sub-sector located between  $d_{last}$  and the interior edge of the Method 1 equal-area sector (e.g., sub-sector  $A_{drem}$  shown in Figures 2H–3 and 2H–4) using Equation 2H–11.

$$A_{drem} = \frac{1}{4}\pi (r - d_{last})^2 - \frac{p - 2}{4p}\pi (r)^2$$
 Eq. 2H-11

For a 16-point traverse (eight points per diameter), Equation 2H-11 may be written as follows:

$$A_{drem} = \frac{1}{4}\pi (r - d_{last})^2 - \frac{3}{16}\pi (r)^2$$
 Eq. 2H-12

Enter the calculated value of  $A_{drem}$  in line 4b of column G of Form 2H–1 or 2H–2.

12.4.6 Calculate the volumetric flow for the sub-sector located between  $d_{\text{last}}$  and the interior edge of the Method 1 equal-area sector, using Equation 2H–13.

$$Q_{drem} = v_{drem} \times A_{drem}$$
 Eq. 2H-13

In Equation 2H–13,  $\mu_{drem}$  is either (1) the measured velocity value at  $d_{rem}$  or (2) the measured velocity at  $d_{last}$ , if the distance between  $d_{drem}$  and  $d_{last}$  is less than or equal to  $\frac{1}{2}$  in. (12.7 mm) and no velocity measurement is taken at  $d_{rem}$  (see section 8.2.4.2). Enter the calculated value of  $Q_{drem}$  in line 4c of column G of Form 2H–1 or 2H–2.

12.4.7 Calculate the total volumetric flow for the Method 1 equal-area sector closest to the wall, using Equation 2H–14.

$$Q_T = Q_{d_1 \rightarrow d_{last}} + Q_{drem}$$
 Eq. 2H-14

Enter the calculated value of  $Q_T$  in line 5a of column G of Form 2H–1 or 2H–2.

12.4.8 Calculate the wall effects-adjusted replacement velocity value for the Method 1 equal-area sector closest to the wall, using Equation 2H–15.

$$\hat{v}e_{j} = \frac{Q_{T}}{\frac{1}{2p}\pi(r)^{2}}$$
 Eq. 2H-15

For a 16-point traverse (eight points per diameter), Equation 2H–15 may be written as follows:

$$\hat{v}e_j = \frac{Q_T}{\frac{1}{16}\pi(r)^2}$$
 Eq. 2H-16

Enter the calculated value of  $\hat{v}e_j$  in line 5b of column G of Form 2H–1 or 2H–2. 12.5 Calculate the wall effects-adjusted average velocity,, by replacing the four values of  $\hat{\mu}_{avg}$  shown in Equation 2H–5 with the four wall effects-adjusted replacement velocity values,  $\hat{\mu}e$ , calculated according to section 12.4.8, using Equation 2H–17.

$$\hat{v}_{avg} = \frac{\left(\sum_{i=1}^{n-4} vi_i + \sum_{j=1}^{4} \hat{v}e_j\right)}{n}$$
 Eq. 2H-17

For a 16-point traverse, Equation 2H–17 may be written as follows:

$$\hat{v}_{avg} = \frac{\left(\sum_{i=1}^{12} vi_i + \sum_{j=1}^{4} \hat{v}e_j\right)}{16}$$
 Eq. 2H-18

12.6 Calculate the wall effects adjustment factor, WAF, using Equation 2H–19.

$$WAF = \frac{\hat{v}_{avg}}{v_{avg}}$$
 Eq. 2H-19

12.6.1 Partial wall effects traverse. If a partial wall effects traverse (see section 8.2.2) is conducted, the value obtained from Equation 2H–19 is acceptable and may be reported as the wall effects adjustment factor provided that the value is greater than or equal to 0.9800. If the value is less than 0.9800, it shall not be used and a wall effects adjustment factor of 0.9800 may be used instead.

12.6.2 Complete wall effects traverse. If a complete wall effects traverse (see section 8.2.3) is conducted, the value obtained from Equation 2H-19 is acceptable and may be reported as the wall effects adjustment factor provided that the value is greater than or equal to 0.9700. If the value is less than 0.9700, it shall not be used and a wall effects adjustment factor of 0.9700 may be used instead. If the wall effects adjustment factor for a particular stack or duct is less than 0.9700, the tester may (1) repeat the wall effects test, taking measurements at more Method 1 traverse points and (2) recalculate the wall effects adjustment factor from these measurements, in an attempt to obtain a wall effects adjustment factor that meets the 0.9700 specification and completely characterizes the wall effects.

12.7 Applying a Wall Effects Adjustment Factor. A default wall effects adjustment factor, as specified in section 8.1, or a calculated wall effects adjustment factor meeting the requirements of section 12.6.1 or 12.6.2 may be used to adjust the average stack gas velocity obtained using Methods 2, 2F, or 2G to take into account velocity decay near the wall of circular stacks or ducts. Default wall effects adjustment factors specified in section 8.1 and calculated wall effects adjustment factors that meet the requirements of section 12.6.1 and 12.6.2 are summarized in Table 2H–2.

12.7.1 Single-run tests. Calculate the final wall effects-adjusted average stack gas velocity for field tests consisting of a single traverse using Equation 2H–20.

$$\hat{\mathbf{v}}_{\text{final}} = \overline{\text{WAF}} \times \mathbf{v}_{\text{avg}}$$
 Eq. 2H-20

The wall effects adjustment factor, WAF, shown in Equation 2H–20, may be (1) a default wall effects adjustment factor, as specified in section 8.1, or (2) a calculated adjustment factor that meets the specifications in sections 12.6.1 or 12.6.2. If a calculated adjustment factor is used in Equation 2H–20, the factor must have been obtained during the same traverse in which  $\mu_{av_{e}}$  or a solution 2.

12.7.2 RATA or other multiple run test procedure. Calculate the final wall effectsadjusted average stack gas velocity for any run k of a RATA or other multiple-run procedure using Equation 2H–21.

$$\hat{v}_{\text{final}(k)} = \overline{\text{WAF}} \times v_{\text{avg}(k)}$$
 Eq. 2H-21

The wall effects adjustment factor, WAF, shown in Equation 2H–21 may be (1) a default wall effects adjustment factor, as specified in section 8.1; (2) a calculated adjustment factor (meeting the specifications in sections 12.6.1 or 12.6.2) obtained from any single run of the RATA that includes run k; or (3) the arithmetic average of more than one WAF (each meeting the specifications in sections 12.6.1 or 12.6.2) obtained through wall effects testing conducted during several runs of the RATA that includes run k. If wall effects adjustment factors (meeting the specifications in sections 12.6.1 or 12.6.2) are determined for more than one RATA run, the arithmetic average of all of the resulting calculated wall effects adjustment factors must be used as the value of WAF and applied to all runs of that RATA. If a calculated, not a default, wall effects adjustment factor is used in Equation 2H-21, the average velocity unadjusted for wall effects,  $\mu_{avg(k)},$  must be obtained from runs in which the number of Method 1 traverse

points sampled does not exceed the number of Method 1 traverse points in the runs used to derive the wall effects adjustment factor,  $W\bar{A}\bar{F}$ , shown in Equation 2H–21.

12.8 Calculating Volumetric Flow Using Final Wall Effects-Adjusted Average Velocity Value. To obtain a stack gas flow rate that accounts for velocity decay near the wall of circular stacks or ducts, replace  $\mu_s$  in Equation 2–10 in Method 2, or  $\mu_{a(avg)}$  a in Equations 2F–10 and 2F–11 in Method 2F, or  $\mu_{a(avg)}$  in Equations 2G–9 and 2G–10 in Method 2G with one of the following.

12.8.1 For single-run test procedures, use the final wall effects-adjusted average stack gas velocity,  $\mu_{final}$ , calculated according to Equation 2H–20.

12.8.2 For RATA and other multiple run test procedures, use the final wall effectsadjusted average stack gas velocity,  $\mu_{final(k)}$ , calculated according to Equation 2H–21.

13.0 Method Performance. [Reserved]

414.0 Pollution Prevention. [Reserved]

15.0 Waste Management. [Reserved]

#### 16.0 Reporting

16.1 Field Test Reports. Field test reports shall be submitted to the Agency according to the applicable regulatory requirements. When Method 2H is performed in conjunction with Method 2, 2F, or 2G to derive a wall effects adjustment factor, a single consolidated Method 2H/2F (or 2H/ 2G) field test report should be prepared. At a minimum, the consolidated field test report should contain (1) all of the general information, and data for Method 1 points, specified in section 16.0 of Method 2F (when Method 2H is used in conjunction with Method 2F) or section 16.0 of Method 2G (when Method 2H is used in conjunction with Method 2 or 2G) and (2) the additional general information, and data for Method 1 points and wall effects points, specified in this section (some of which are included in section 16.0 of Methods 2F and 2G and are repeated in this section to ensure complete reporting for wall effects testing).

16.1.1 Description of the source and site. The field test report should include the descriptive information specified in section 16.1.1 of Method 2F (when using Method 2F) or 2G (when using either Method 2 or 2G). It should also include a description of the stack or duct's construction material along with the diagram showing the dimensions of the stack or duct at the test port elevation prescribed in Methods 2F and 2G. The diagram should indicate the location of all wall effects traverse points where measurements were taken as well as the Method 1 traverse points. The diagram should provide a unique identification number for each wall effects and Method 1 traverse point, its distance from the wall, and its location relative to the probe entry ports.

16.1.2 Field test forms. The field test report should include a copy of Form 2H–1, 2H–2, or an equivalent for each Method 1 exterior equal-area sector.

16.1.3 Field test data. The field test report should include the following data for the Method 1 and wall effects traverse.

16.1.3.1 Data for each traverse point. The field test report should include the values

specified in section 16.1.3.2 of Method 2F (when using Method 2F) or 2G (when using either Method 2 or 2G) for each Method 1 and wall effects traverse point. The provisions of section 8.4.2 of Method 2H apply to the temperature measurements reported for wall effects traverse points. For each wall effects and Method 1 traverse point, the following values should also be included in the field test report.

(a) Traverse point identification number for each Method 1 and wall effects traverse point.

(b) Probe type.

(c) Probe identification number.

(d) Probe velocity calibration coefficient (i.e.,  $C_p$  when Method 2 or 2G is used;  $F_2$  when Method 2F is used).

For each Method 1 traverse point in an exterior equal-area sector, the following additional value should be included. (e) Calculated replacement velocity,  $\hat{v}e_{i}$ ,

accounting for wall effects. 16.1.3.2 Data for each run. The values

specified in section 16.1.3.3 of Method 2F (when using Method 2F) or 2G (when using either Method 2 or 2G) should be included in the field test report once for each run. The provisions of section 12.8 of Method 2H apply for calculating the reported gas volumetric flow rate. In addition, the following Method 2H run values should also be included in the field test report.

(a) Average velocity for run, accounting for wall effects,  $\hat{v}_{avg}$ .

(b) Wall effects adjustment factor derived from a test run, WAF.

16.1.3.3 Data for a complete set of runs. The values specified in section 16.1.3.4 of Method 2F (when using Method 2F) or 2G (when using either Method 2 or 2G) should be included in the field test report once for each complete set of runs. In addition, the field test report should include the wall effects adjustment factor,  $W\bar{A}\bar{F}$ , that is applied in accordance with section 12.7.1 or 12.7.2 to obtain the final wall effects-adjusted average stack gas velocity  $\hat{y}_{final}$  or  $\hat{y}_{final(k)}$ .

16.1.4 Quality assurance and control. Quality assurance and control procedures, specifically tailored to wall effects testing, should be described.

16.2 Reporting a Default Wall Effects Adjustment Factor. When a default wall effects adjustment factor is used in accordance with section 8.1 of this method, its value and a description of the stack or duct's construction material should be reported in lieu of submitting a test report. 17.0 *References.*

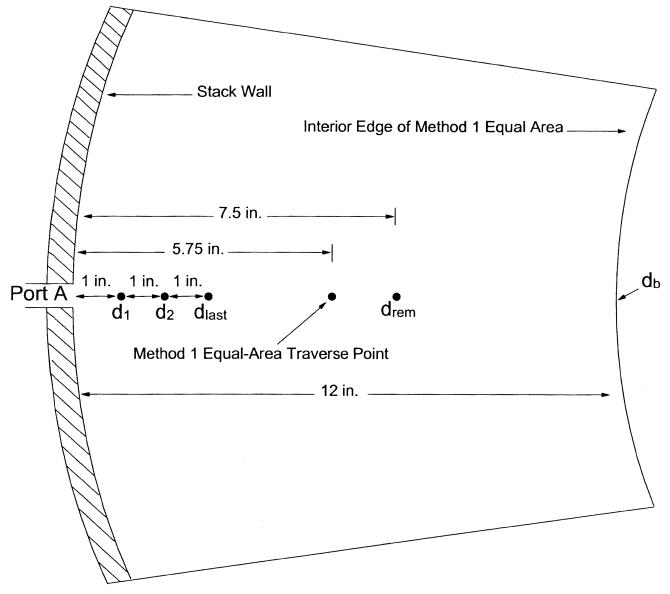

Figure 2H-2. Figure showing part of a Method 1 equal-area sector closest to the stack wall with three illustrative wall effects points at 1 in. intervals, the Method 1 equal-area traverse point, and  $d_{rem}$  for a 15 ft diameter stack.<sup>1</sup>

<sup>&</sup>lt;sup>1</sup> Metric equivalents of English units used in Figure 2H-2 are as follows: 1 in. = 2.5 cm; 5.75 in. = 14.6 cm; 7.5 in. = 19.0 cm; 12 in. = 30.5 cm; and 15 ft = 4.6 m.

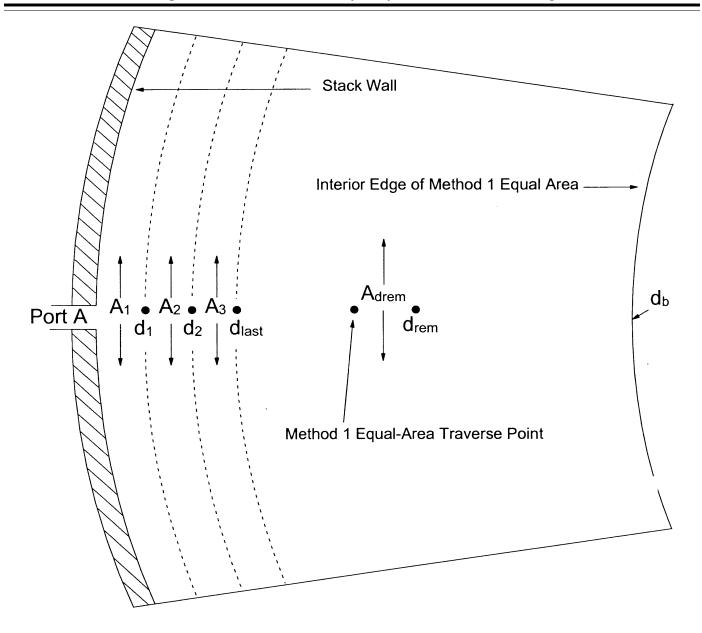

Figure 2H-3. Figure showing part of a Method 1 equal-area sector closest to the stack wall with three illustrative sub-sectors between the stack wall and  $d_{last}$  and the sub-sector represented by  $d_{rem}$ .  $A_1$  is the area between the stack wall and  $d_1$ ,  $A_2$  is the area between  $d_1$  and  $d_2$ ,  $A_3$  is the area between  $d_2$  and  $d_{last}$ , and  $A_{drem}$  is the area between  $d_{last}$  and the interior edge of the Method 1 equal-area sector.

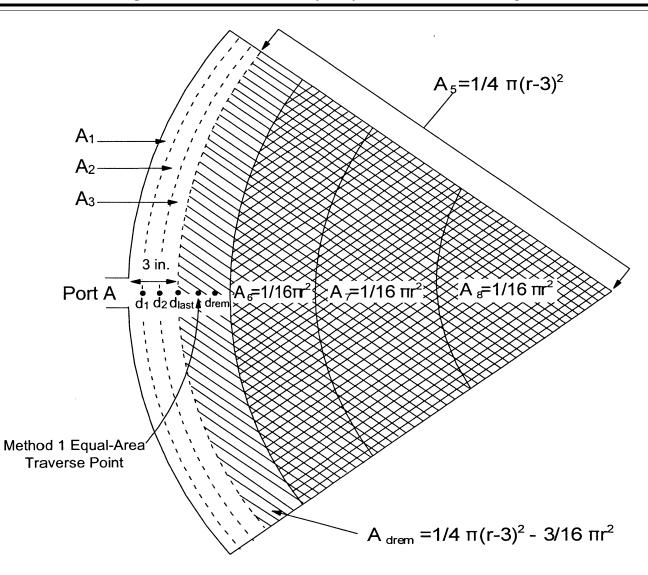

Figure 2H-4. Figure illustrating the calculations in Equation 2H-12 used to calculate the cross sectional area of the sub-sector between  $d_{last}$  and the interior edge of the Method 1 sector closest to the stack wall  $(A_{drem})$  for a 16-point Method 1 traverse. The Method 1 equal-area traverse point and four wall effects traverse points  $(d_1, d_2, d_{last})$  and  $d_{rem}$  within the Method 1 sector closest to the stack wall are also shown.<sup>1</sup>

<sup>&</sup>lt;sup>1</sup> All dimensions are given in in. Metric equivalents (in cm) are as follows: 3 in. = 7.6 cm;  $A_5 = 1/4 \pi (r-7.6)^2$ ; and  $A_{drem} = 1/4 \pi (r-7.6)^2 - 3/16 \pi r^2$ .

## Form 2H-1. Calculation of Wall Effects Replacement Velocity Values (16-Point Method 1 Traverse)
